# Recap: Neural Networks

Element-wise sigmoid

$$\sigma(v) = [\sigma(v_1), \sigma(v_2), \dots, \sigma(v_h)]$$

- Hidden layer: A bunch of logistic regression classifiers
  - Parameters:  $w_j$  and  $b_j$  for each classifier
  - Equivalently: matrix  $W$  ( $h \times d$ ) and vector  $b$  (length  $h$ )
  - Produces “activations” = learned feature vector
- Final layer: A linear classifier
  - E.g. if logistic regression, has parameter vector  $v$  and bias  $c$
- **Parameters of model are  $\theta = (W, b, v, c)$**

# Recap: Stochastic gradient descent

General loss function:  $\frac{1}{n} \sum_{i=1}^n \ell\left(y^{(i)}, g(x^{(i)})\right)$

Model's output, depends on parameters  $\theta$

## Gradient Descent

$$\theta \leftarrow \theta - \eta \cdot \underbrace{\frac{1}{n} \sum_{i=1}^n \nabla_{\theta} \ell\left(y^{(i)}, g(x^{(i)})\right)}_{\text{Average of per-example gradients}}$$

- Disadvantage: 1 update is  $O(n)$  time
  - What if dataset is very large?
  - Idea: Approximate with sample mean

## Stochastic Gradient Descent

1. Sample a *batch*  $B$  of examples from the training dataset
2. Do the update

$$\theta \leftarrow \theta - \eta \cdot \underbrace{\frac{1}{|B|} \sum_{(x,y) \in B} \nabla_{\theta} \ell(y, g(x))}_{\text{Sample mean within batch}}$$

Sample mean within batch

# Today: How to compute gradients?

---

$$\theta \leftarrow \theta - \eta \cdot \frac{1}{|B|} \sum_{(x,y) \in B} \nabla_{\theta} \ell(y, g(x))$$

How to compute  
this gradient?

- Taking gradients by hand is tedious, and we have to re-do it every time we want to change the “architecture”
  - Change number of layers
  - Change from sigmoid to tanh
  - Etc...
- Let’s make a program do it for us!

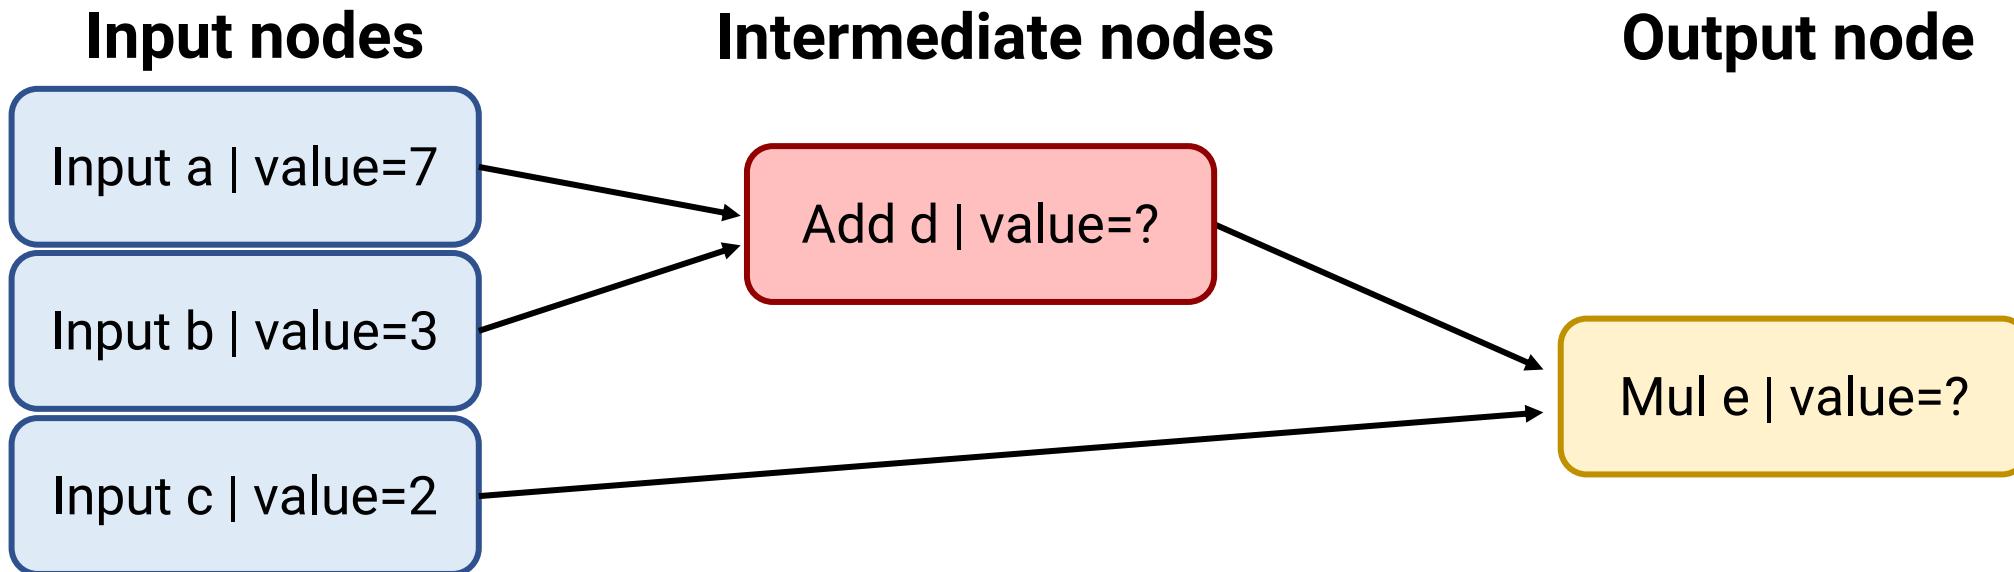

# Today's Plan

---

- The computation graph
- Backpropagation on trees
- Backpropagation on DAGs

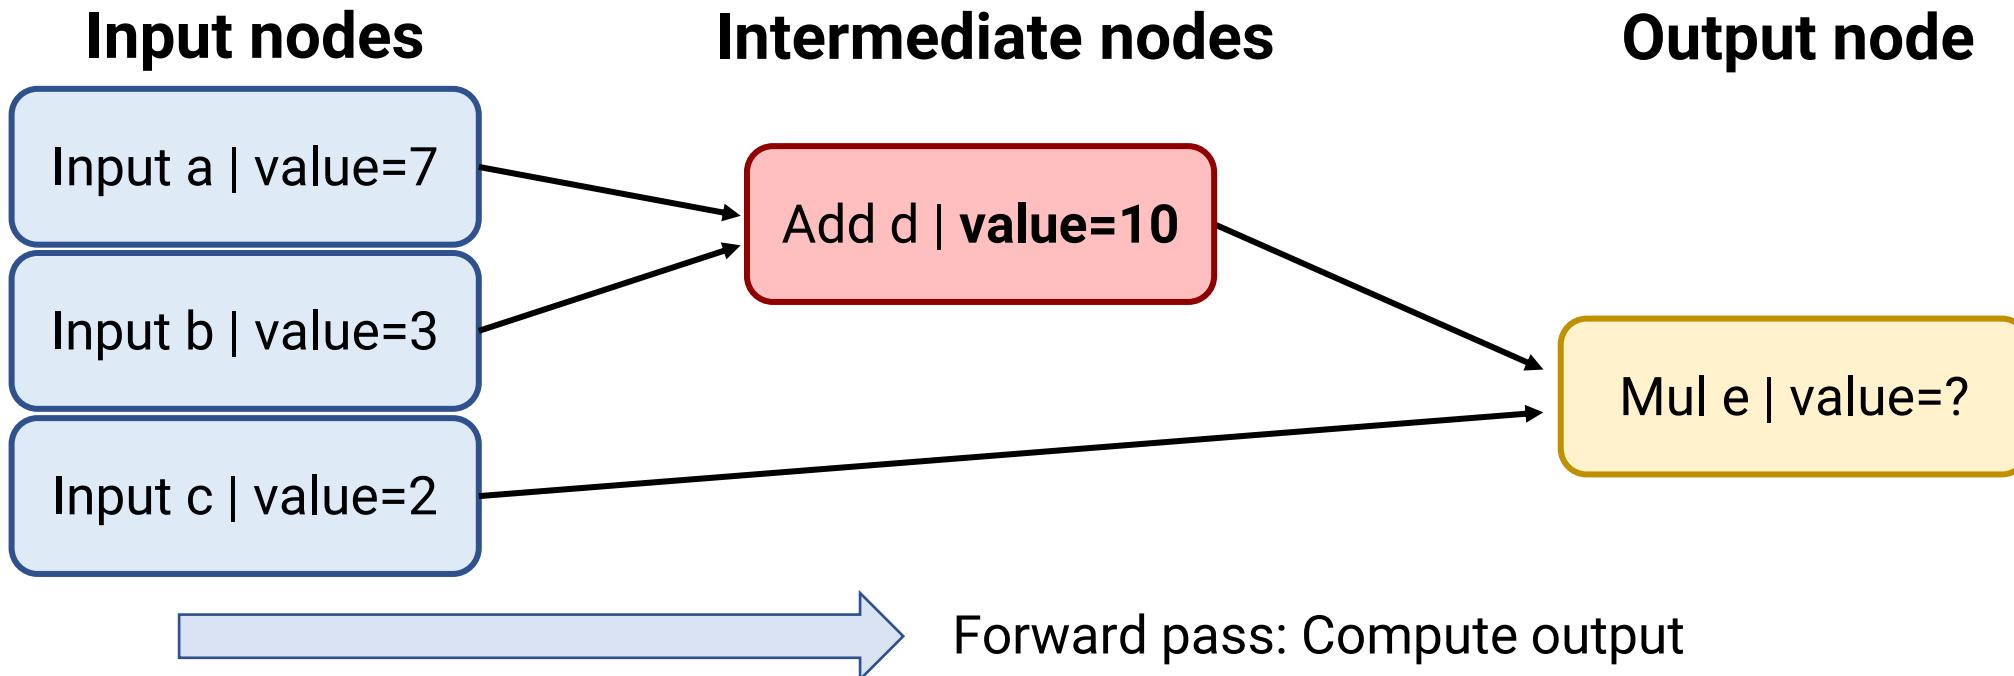

# Computation Graph

Computation graph for  $(a + b) * c$  when  $a=7, b=3, c=2$

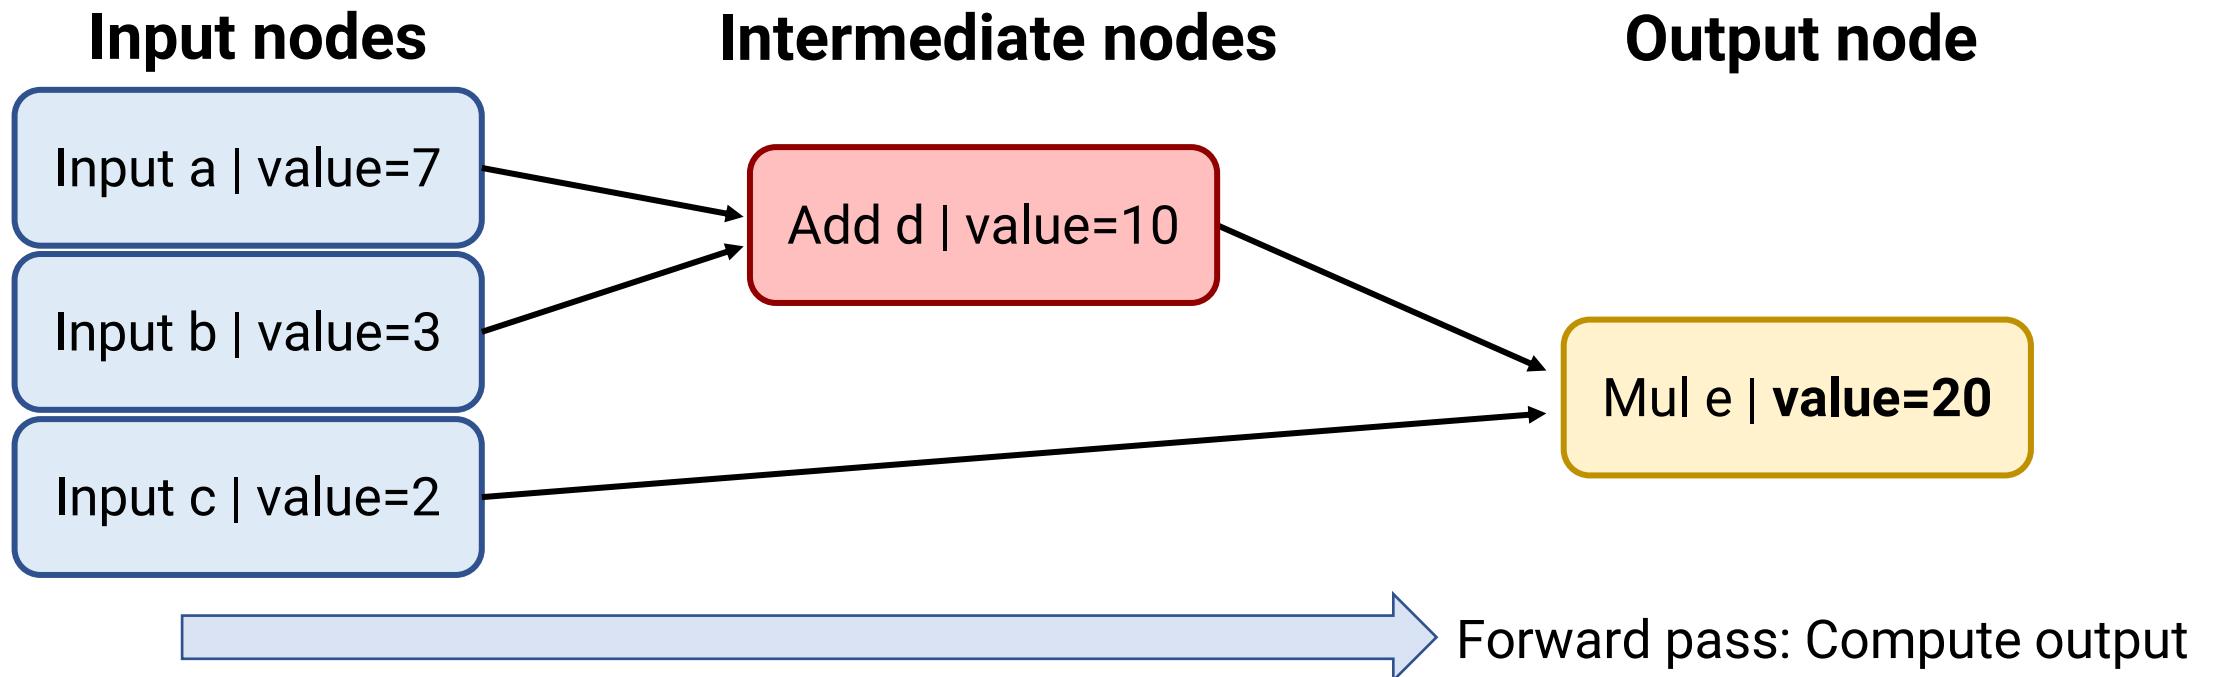

# Computation Graph

Computation graph for  $(a + b) * c$  when  $a=7, b=3, c=2$

# Computation Graph

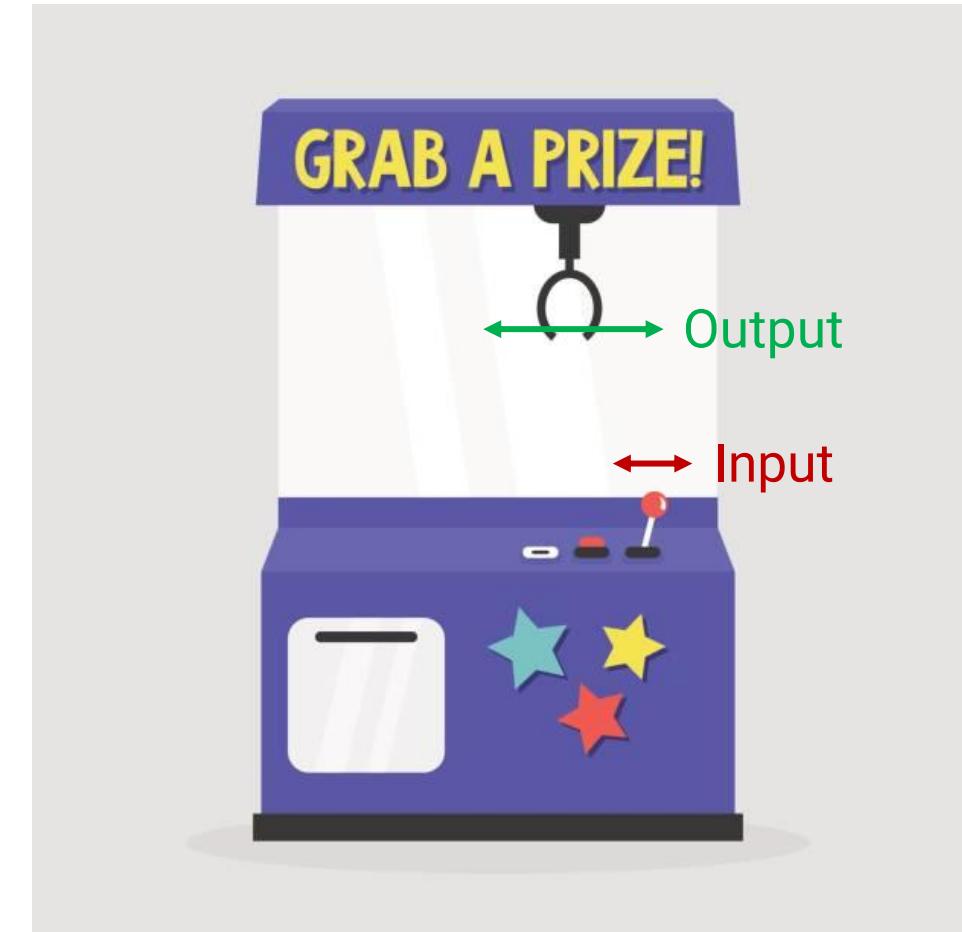

Computation graph for  $(a + b) * c$  when  $a=7, b=3, c=2$

# Gradient checking

---

- **Numerical gradients:** A simpler but less efficient way to compute gradients
- What does  $\partial y / \partial x$  mean?
  - If I change  $x$  by epsilon, by what proportion of epsilon does  $y$  change?
- We can just compute this for every input node!
- Pro: Easy to implement, useful to check correctness
- Con: Slow—requires  $O(\# \text{inputs})$  function evaluations

# Let's implement!

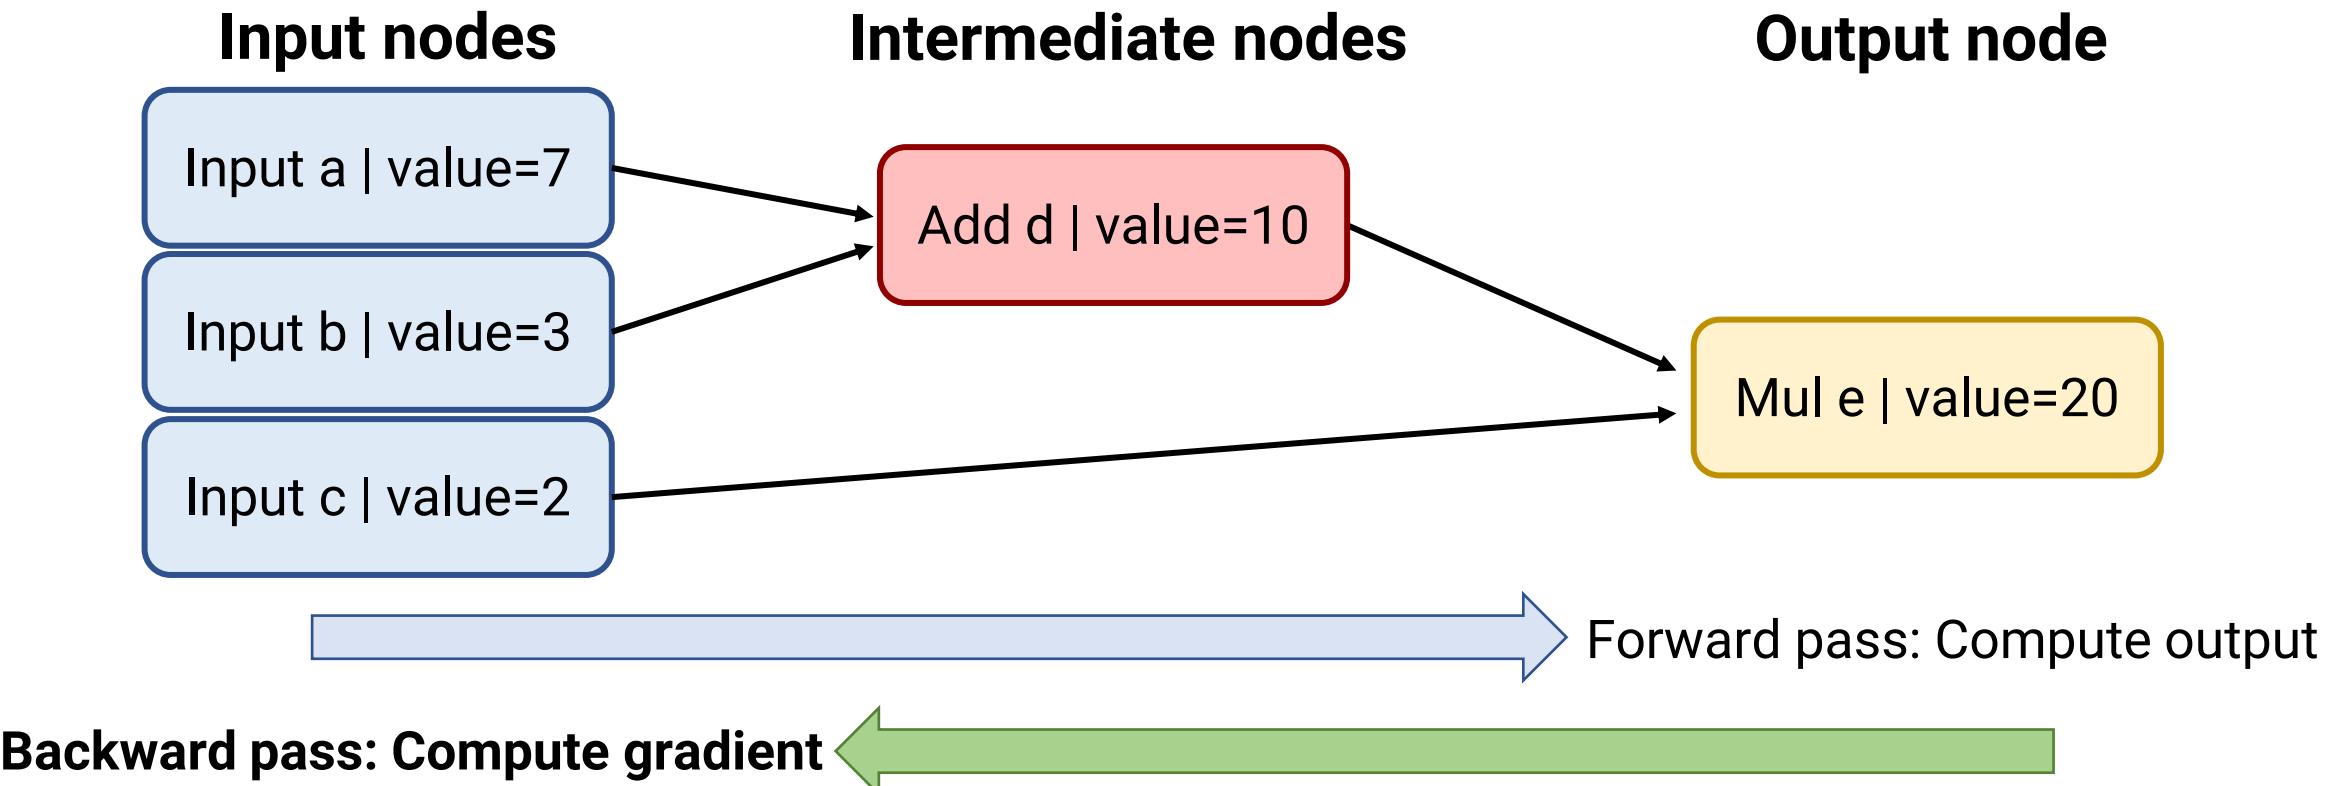

# Today's Plan

---

- The computation graph
- Backpropagation on trees
- Backpropagation on DAGs

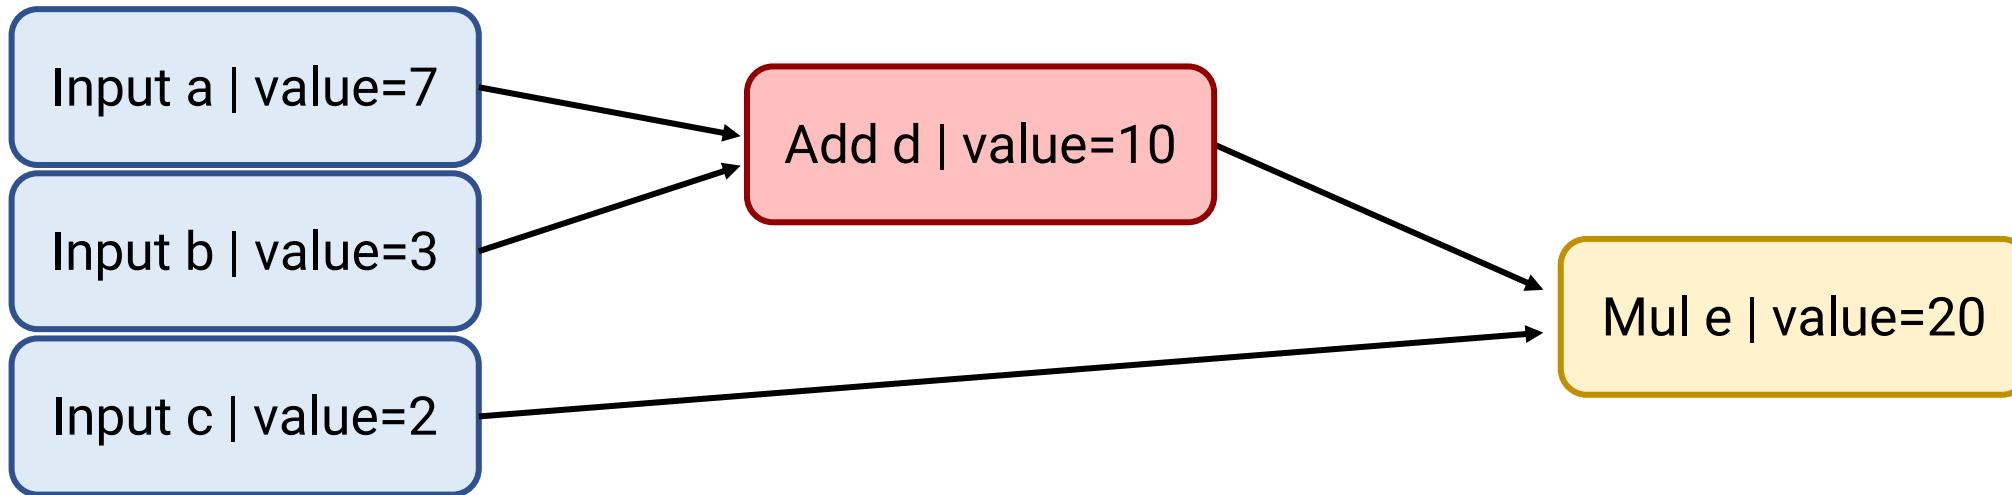

# Computation Graph

Computation graph for  $(a + b) * c$  when  $a=7, b=3, c=2$

# Backpropagation on trees

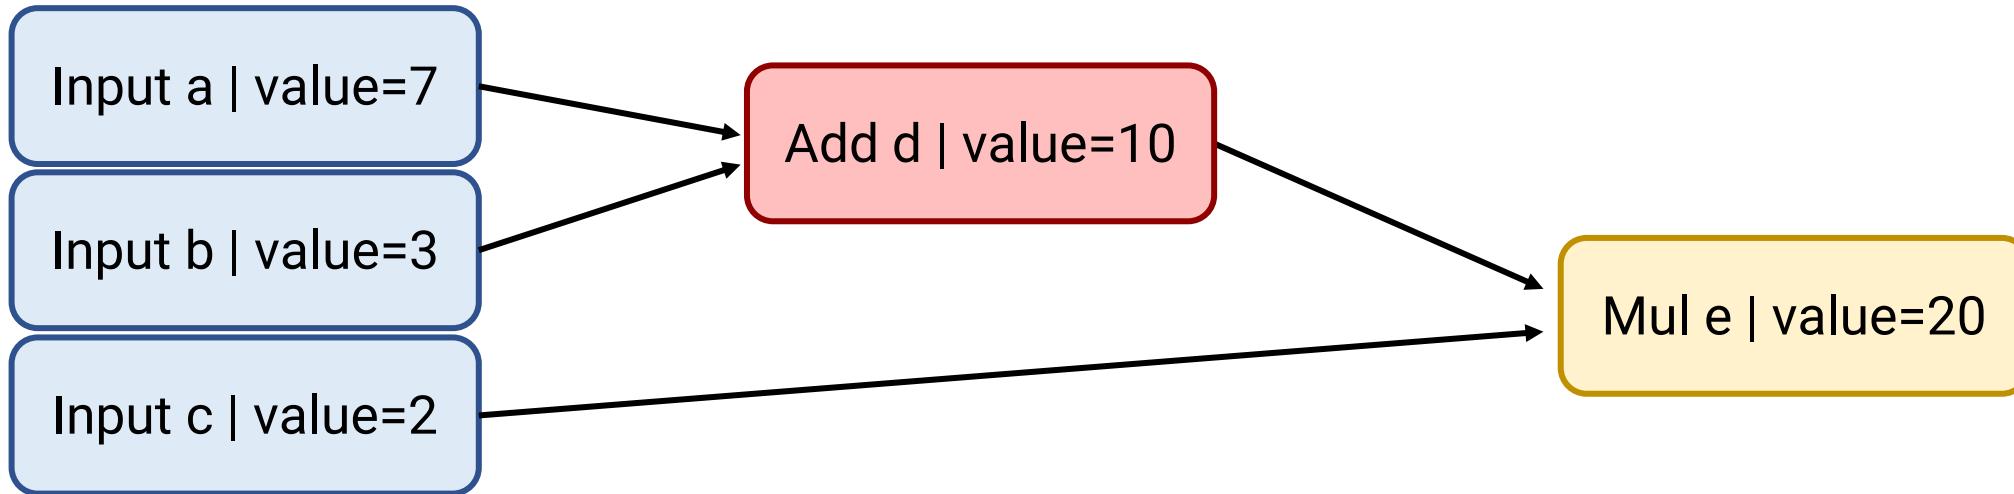

---

- For now: assume that the computation graph is a tree
  - Each node is only used in a single computation
  - Root of tree is output
  - Leaves of tree are inputs
- Idea: Recursively compute  $\partial(\text{output})/\partial(\text{node})$  for each node, starting at output

# Backpropagation on trees

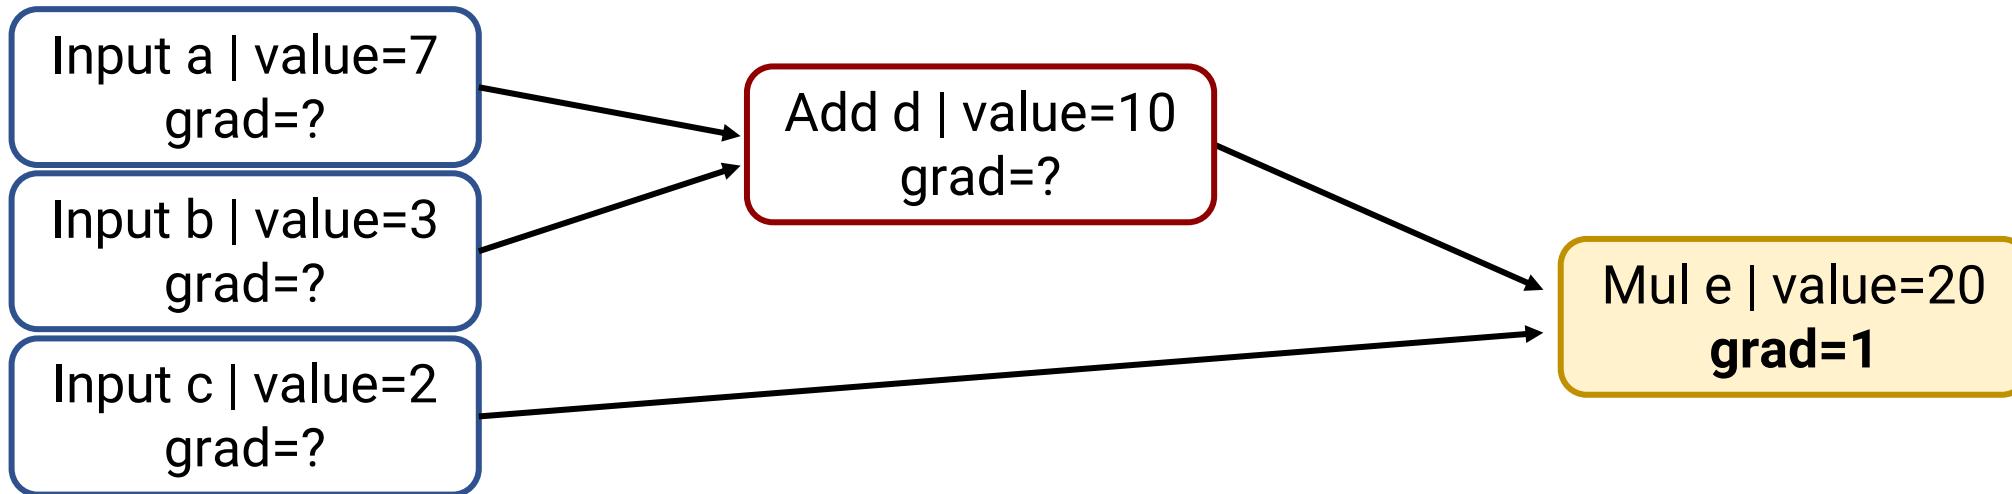

---

- Goal: Compute gradient  $[\partial e / \partial a, \partial e / \partial b, \partial e / \partial c]$

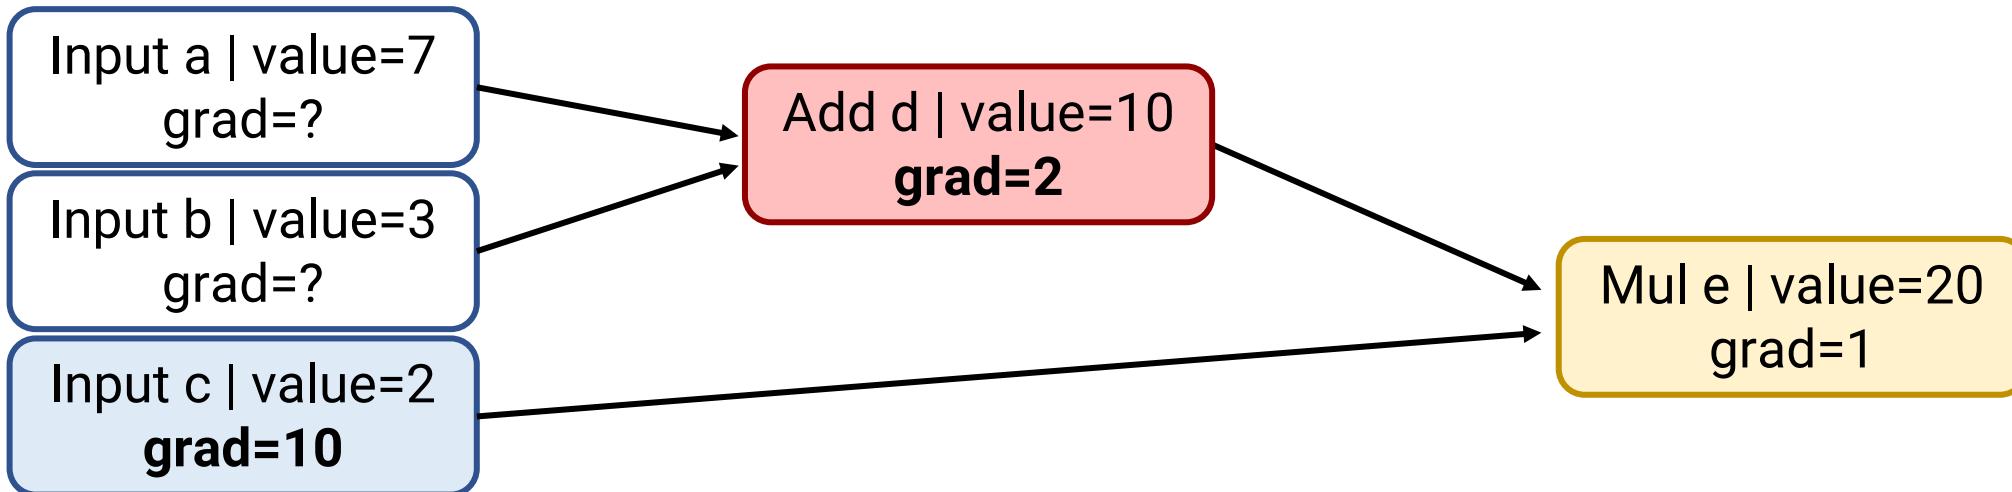

# Backpropagation on trees

---

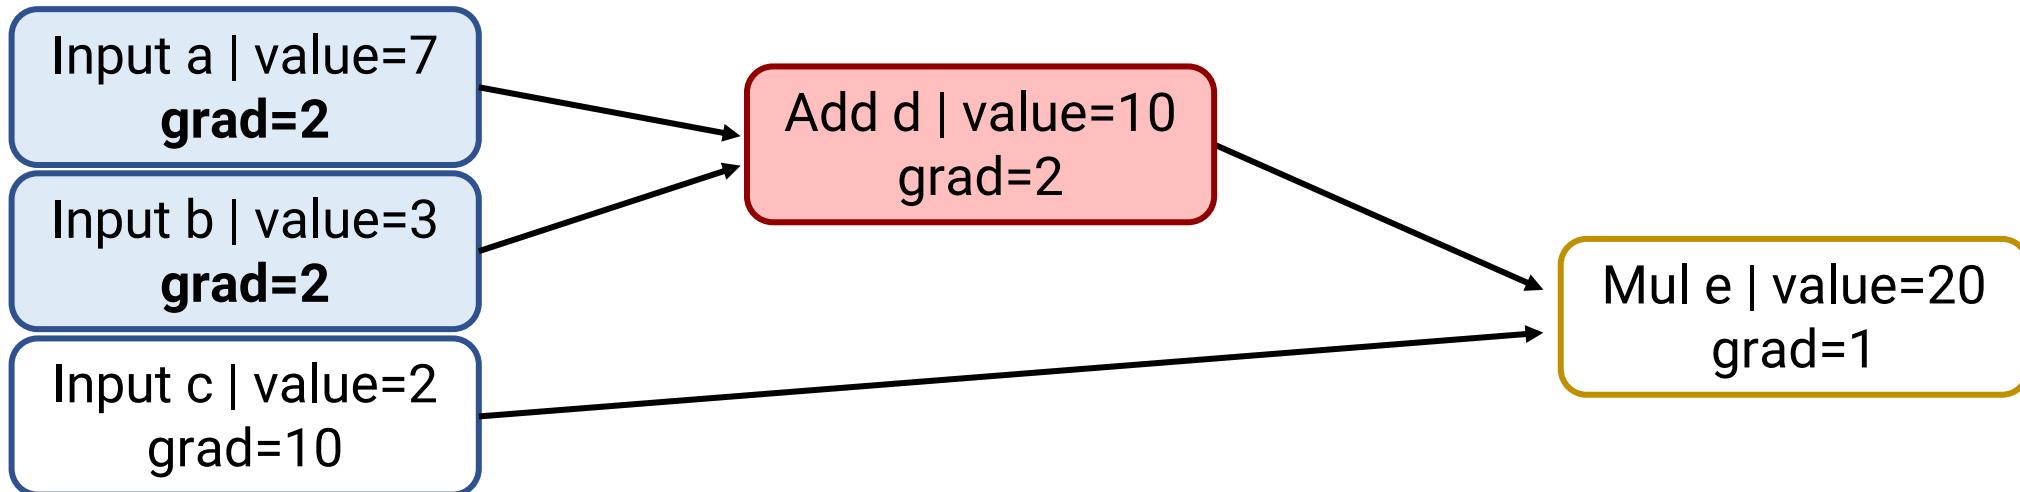

- Goal: Compute gradient  $[\partial e / \partial a, \partial e / \partial b, \partial e / \partial c]$
- Step 1: Base case:  $\partial e / \partial e = 1$

# Backpropagation on trees

- Goal: Compute gradient  $[\partial e / \partial a, \partial e / \partial b, \partial e / \partial c]$
- Step 2: How does **Mul** (node e) “distribute” gradient to its children?
  - $\partial(x*y)/\partial x = y$
  - Chain Rule:  $\partial(out)/\partial x = \partial(out)/\partial(x*y) * \partial(x*y)/\partial x = \partial(out)/\partial(x*y) * y$
  - General rule: Child gets parent's gradient \* value of other child

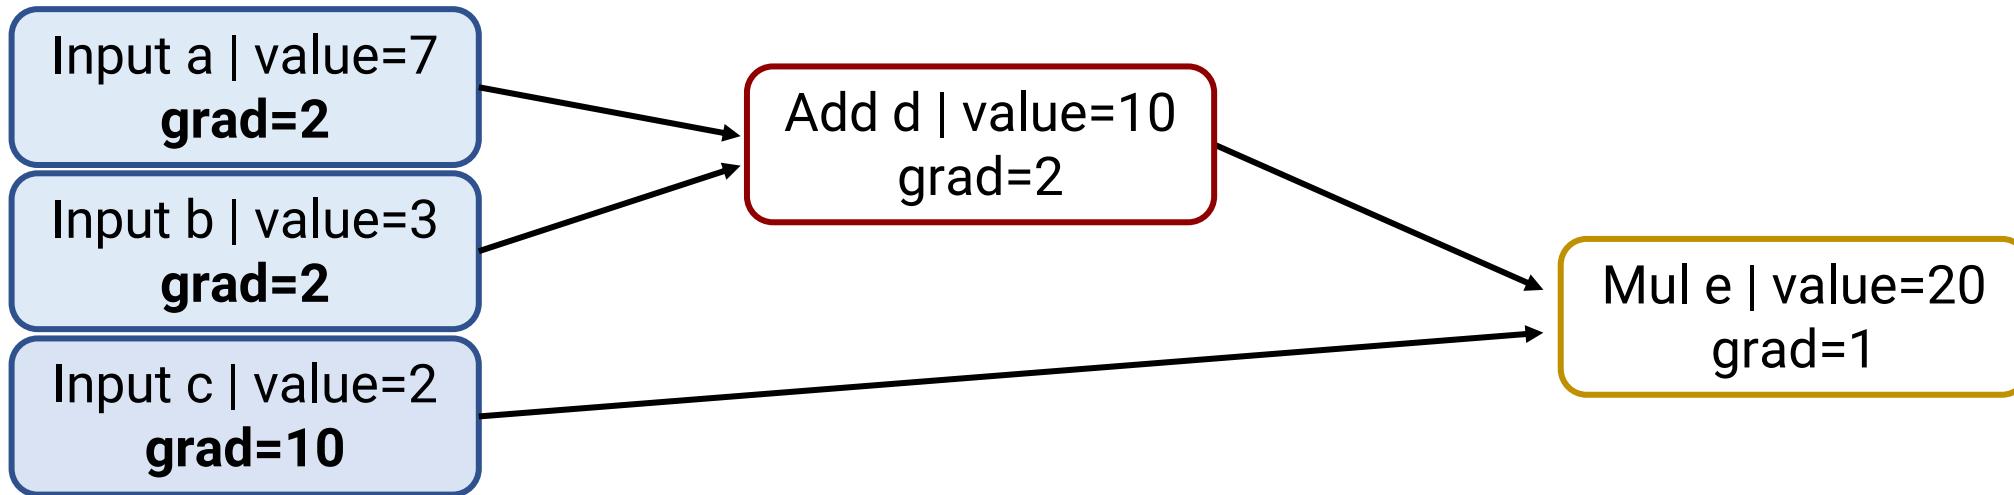

# Backpropagation on trees

- Goal: Compute gradient  $[\partial e / \partial a, \partial e / \partial b, \partial e / \partial c]$
- Step 3: How does **Add** (node d) “distribute” gradient to its children?
  - $\partial(x+y)/\partial x = 1$
  - Chain Rule:  $\partial(\text{out})/\partial x = \partial(\text{out})/\partial(x+y) * \partial(x+y)/\partial x = \partial(\text{out})/\partial(x+y) * 1$
  - General rule: Child gets parent's gradient \* 1

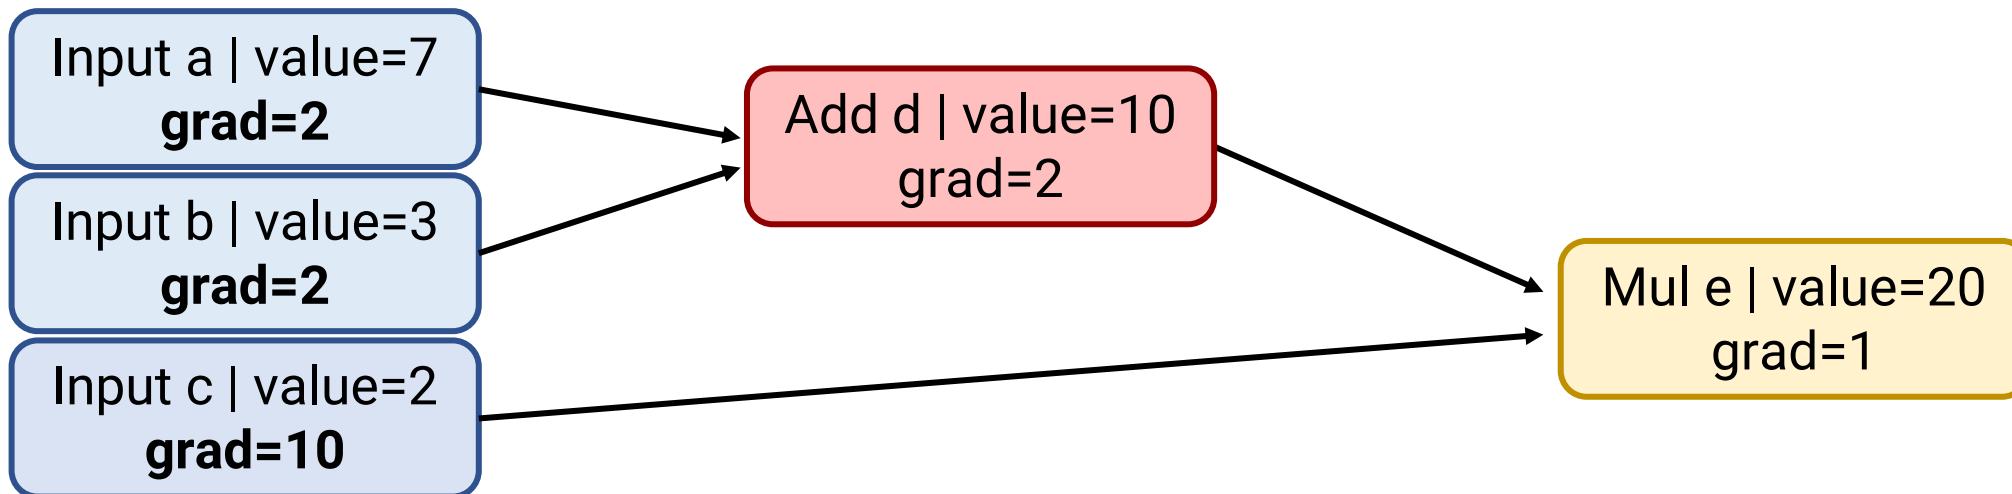

# Backpropagation on trees

---

- Goal: Compute gradient  $[\partial e / \partial a, \partial e / \partial b, \partial e / \partial c]$
- Step 4: Leaf nodes
  - Don't need to do anything

# Backpropagation on trees

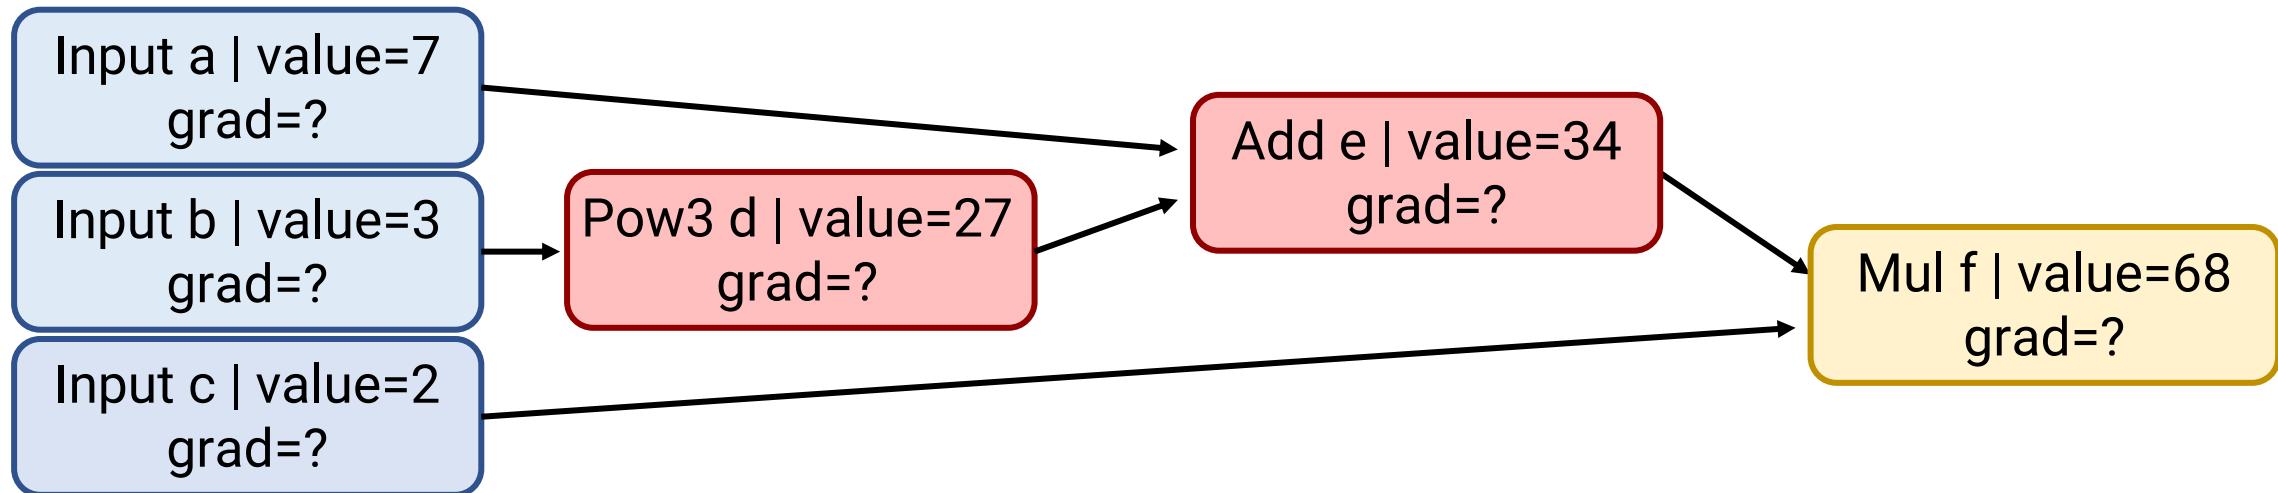

- Goal: Compute gradient  $[\partial e / \partial a, \partial e / \partial b, \partial e / \partial c]$
- Overall Recipe
  - Do forward pass
  - Start at root and recurse over children
  - Each node knows how to take **gradient of itself** with respect to each child
  - By Chain Rule,  $\text{child.grad} = \text{parent.grad} * \partial(\text{parent}) / \partial(\text{child})$

# Let's implement!

# PowerNode

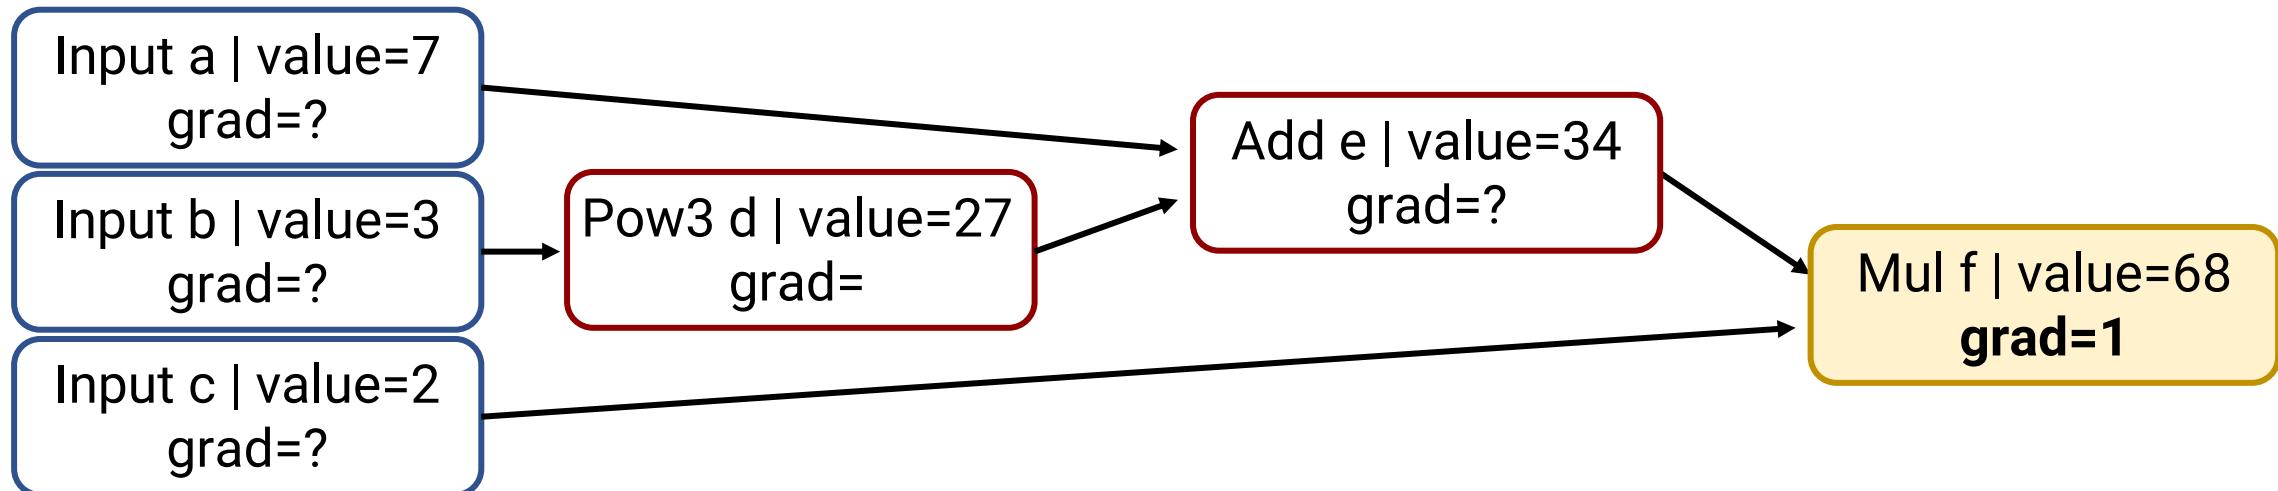

---

New function:  $(a + b^3) * c$  where  $a=7, b=3, c=2$

# PowerNode

---

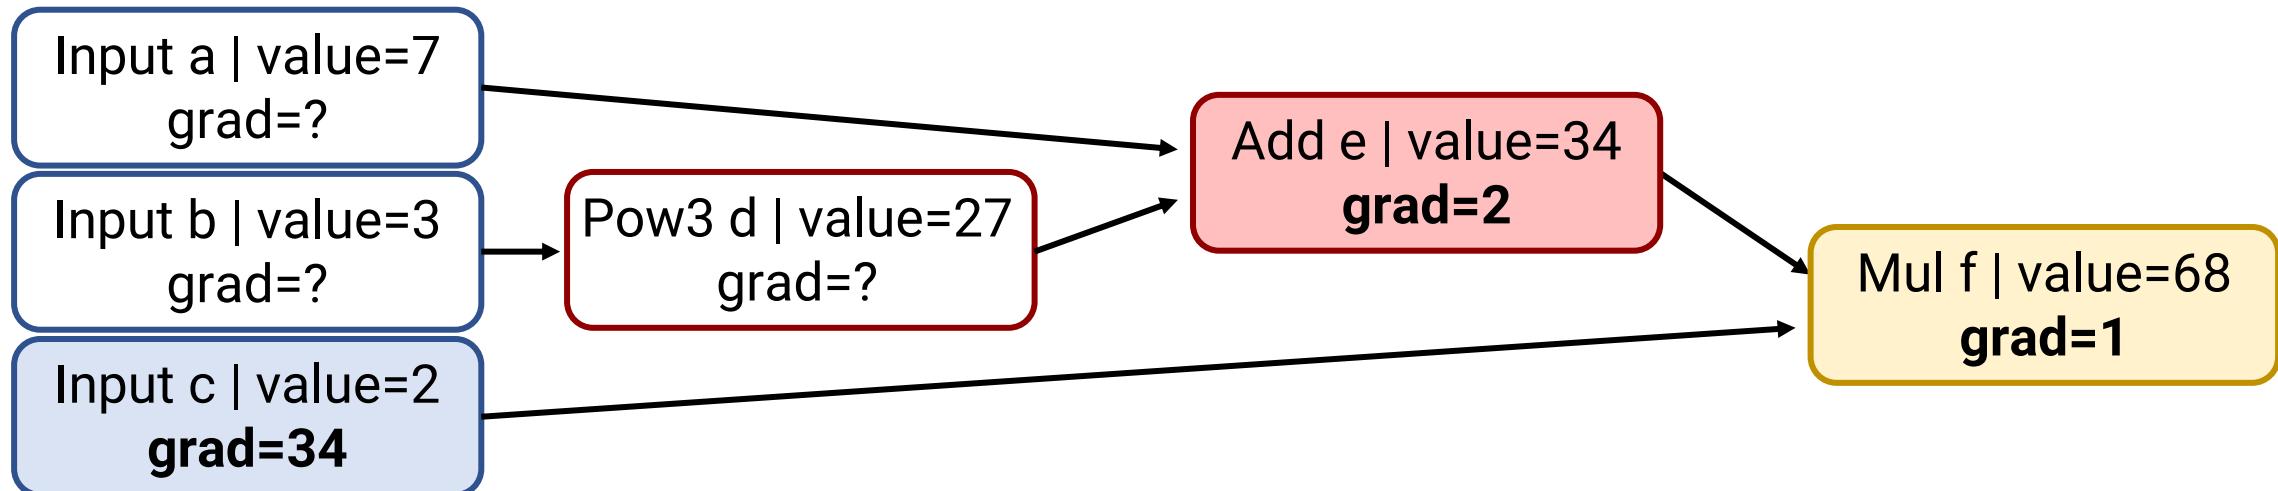

New function:  $(a + b^3) * c$  where  $a=7, b=3, c=2$

- Goal: Compute gradient  $[\partial f / \partial a, \partial f / \partial b, \partial f / \partial c]$
- Step 1: Base case:  $\partial f / \partial f = 1$

# PowerNode

---

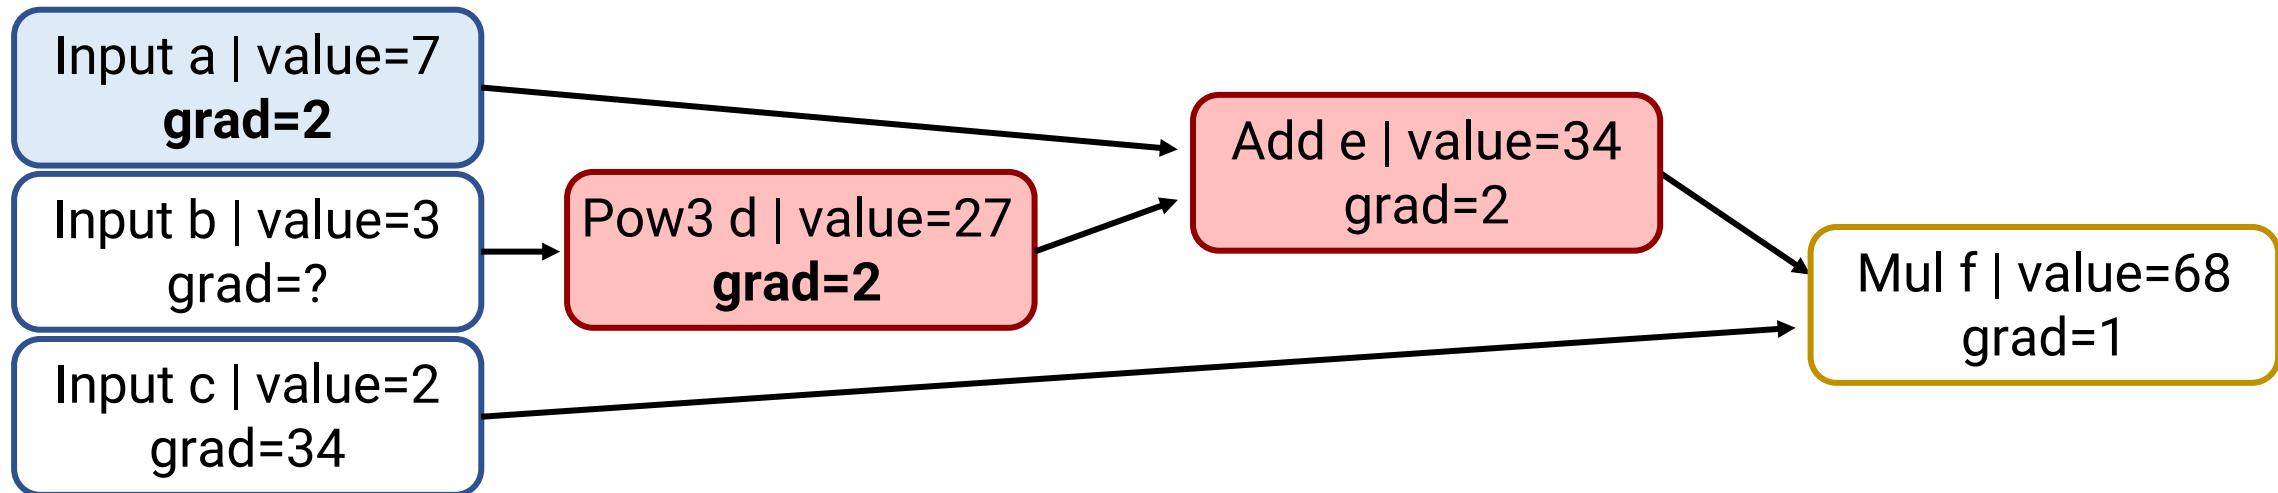

New function:  $(a + b^3) * c$  where  $a=7, b=3, c=2$

- Goal: Compute gradient  $[\partial f / \partial a, \partial f / \partial b, \partial f / \partial c]$
- Step 2: Distribute **Mul** (node f) gradient to children

# PowerNode

---

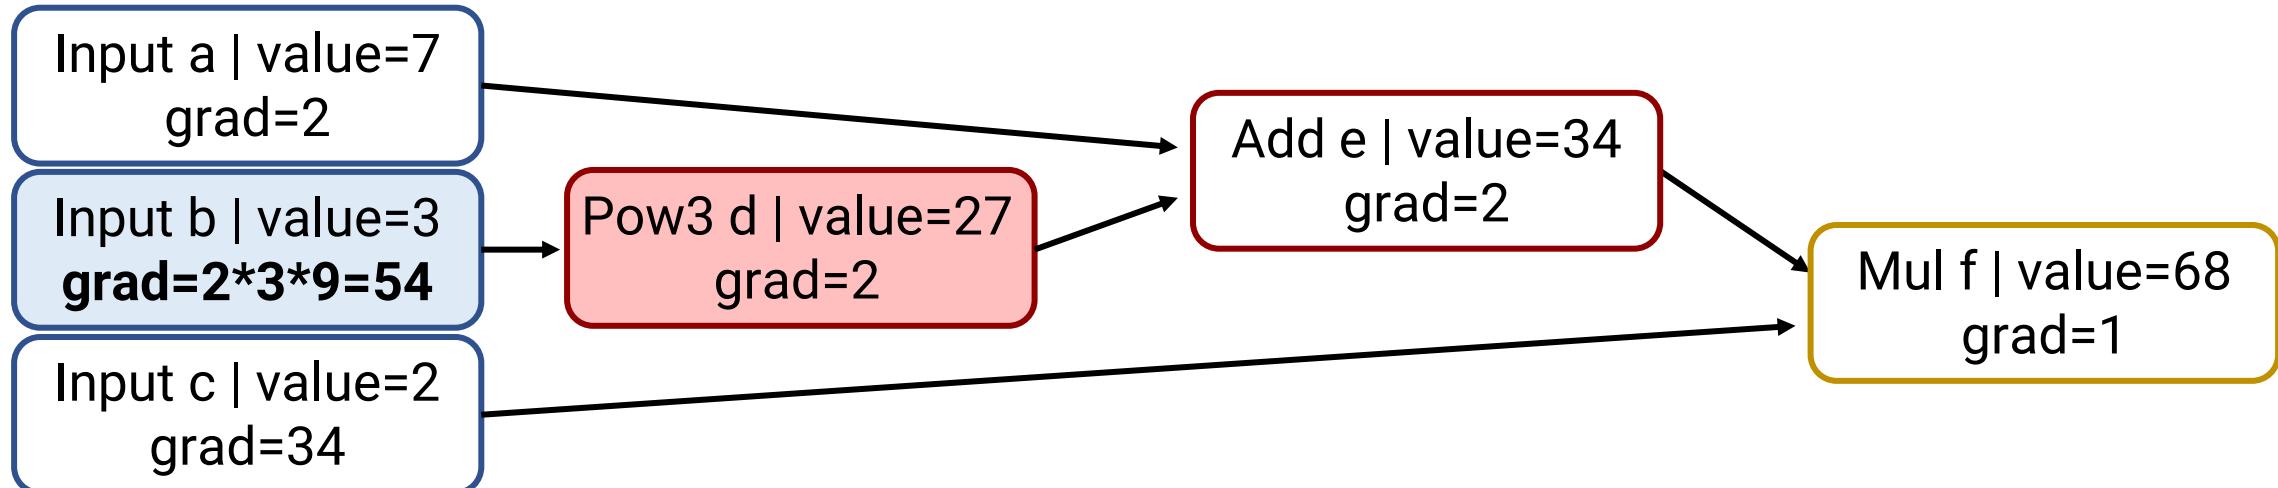

New function:  $(a + b^3) * c$  where  $a=7, b=3, c=2$

- Goal: Compute gradient  $[\partial f / \partial a, \partial f / \partial b, \partial f / \partial c]$
- Step 3: Distribute **Add** (node e) gradient to children

# PowerNode

---

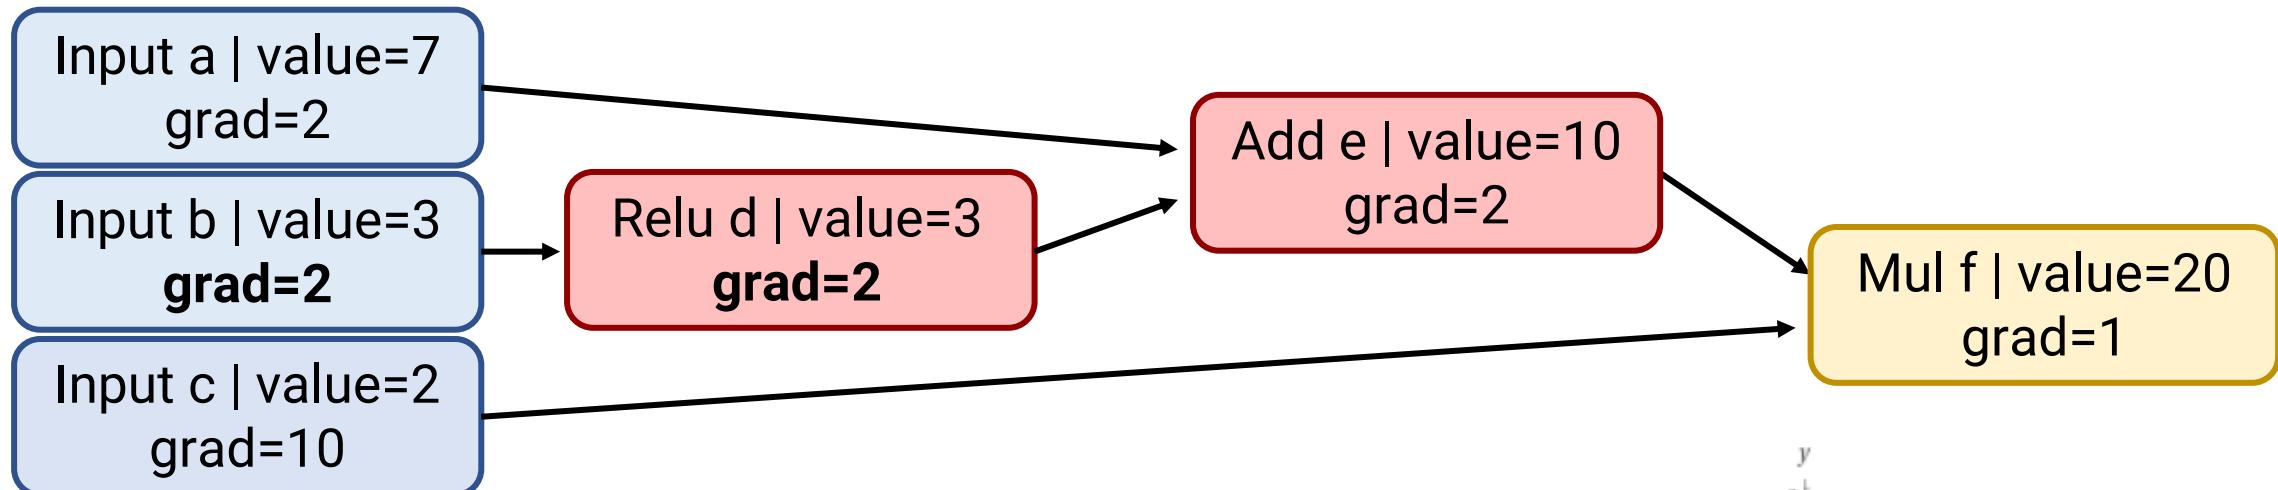

New function:  $(a + b^3) * c$  where  $a=7, b=3, c=2$

- Goal: Compute gradient  $[\partial f / \partial a, \partial f / \partial b, \partial f / \partial c]$
- Step 4: Distribute **Pow3** (node d) gradient to children
  - $\partial(x^p) / \partial x = p * x^{p-1}$
  - By Chain Rule: Child gets parent's gradient \*  $p * child^{p-1}$

# Let's implement!

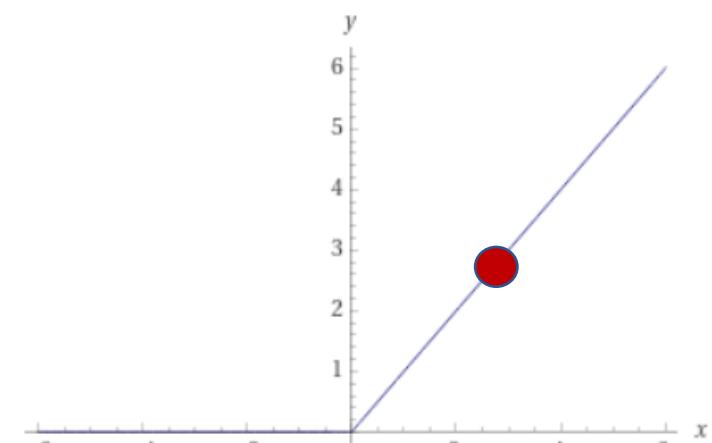

# ReluNode

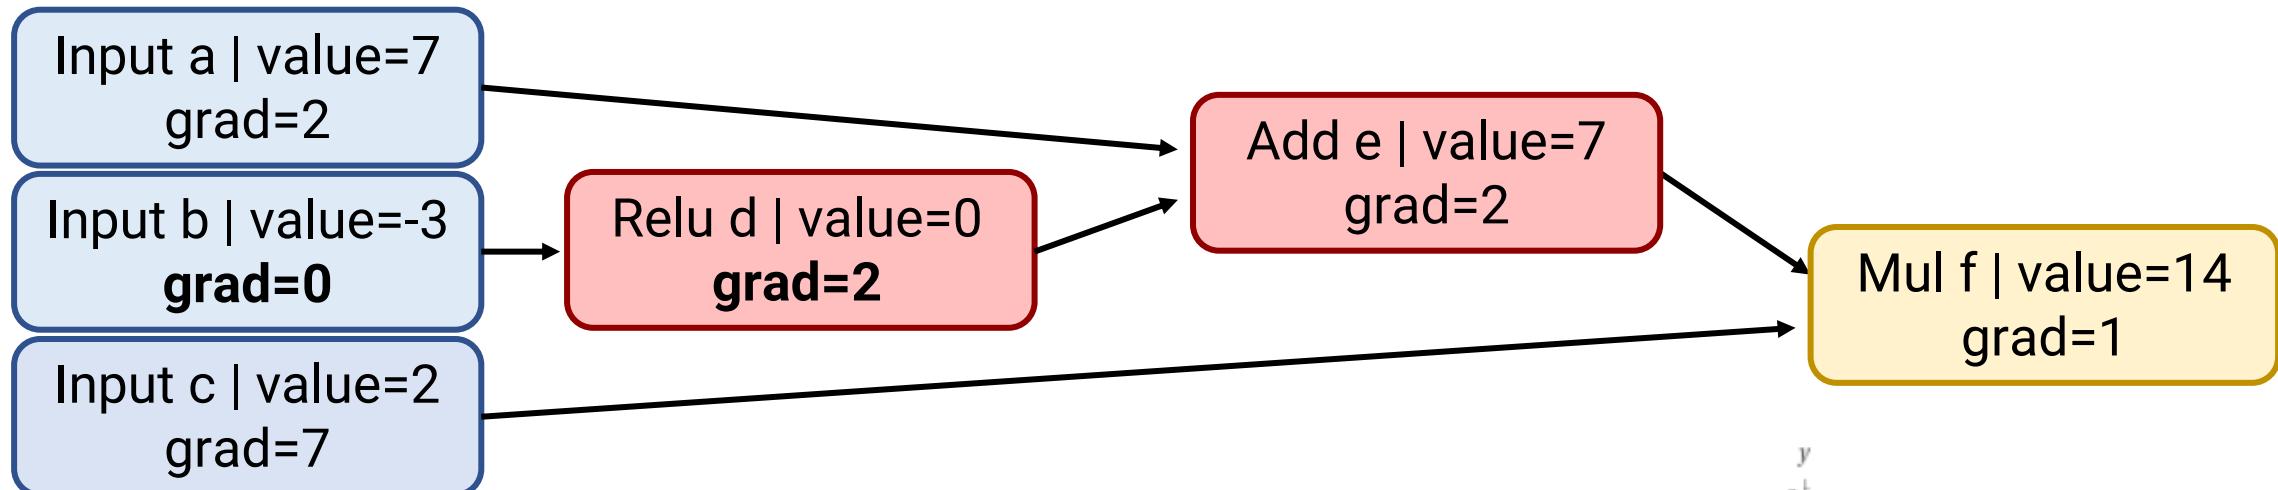

New function:  $(a + \text{Relu}(b)) * c$  where  $a=7, b=3, c=2$

- Steps 1-3 are the same
- Step 4: Relu
  - $\partial(\text{Relu}(x))/\partial x = 1 \text{ if } x > 0, 0 \text{ if } x \leq 0$
  - If child > 0, child.grad = parent.grad \* 1
  - If child ≤ 0, child.grad = 0

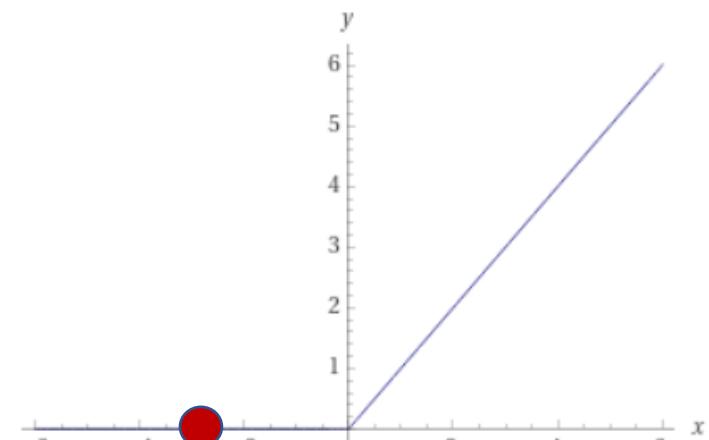

$$\text{ReLU}(z) = \max(z, 0)$$

# ReluNode

New function:  $(a + \text{Relu}(b)) * c$  where  $a=7, b=-3, c=2$

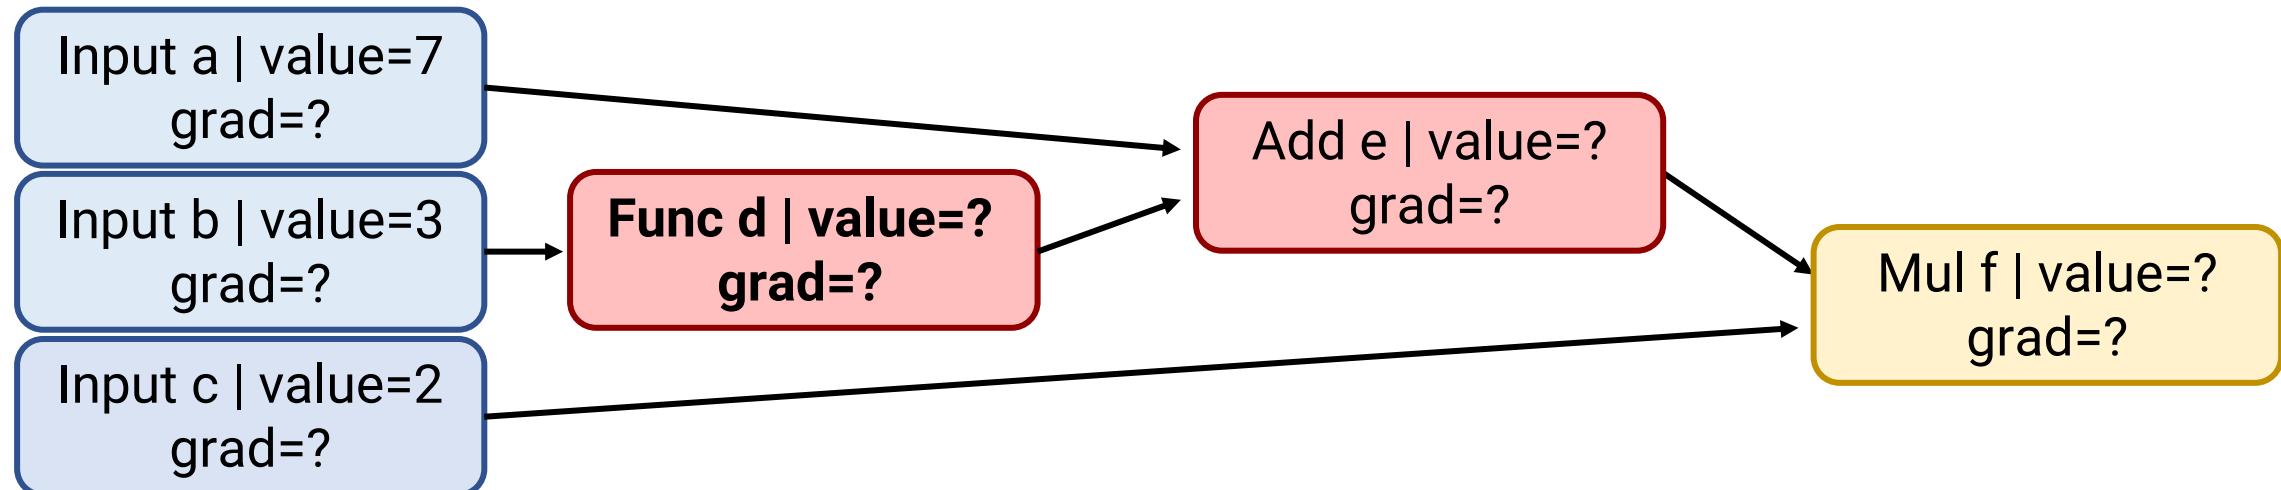

- Steps 1-3 are the same
- Step 4: Relu
  - $\partial(\text{Relu}(x))/\partial x = 1 \text{ if } x > 0, 0 \text{ if } x \leq 0$
  - If child > 0, child.grad = parent.grad \* 1
  - **If child  $\leq 0$ , child.grad = 0**

$$\text{ReLU}(z) = \max(z, 0)$$

# Generic Unary Function

---

New function:  $(a + \text{Func}(b)) * c$  where  $a=7, b=3, c=2$

- Steps 1-3 are the same
- Step 4: Func (generic function)
  - $\text{child.grad} = \text{parent.grad} * \partial(\text{Func}(\text{child}))/\partial\text{child}$

# Announcements

---

- Homework 2 Problems 1-3 released
  - Problem 4 will be released shortly
  - Due Thursday, March 2
- Midterm in class Thursday, March 9
  - Allowed one double-sided 8.5x11 sheet of notes
  - Material covered through March 2 (but not March 7)
  - I highly recommend writing this yourself (good for memory)
- New CP: Aman Bansal

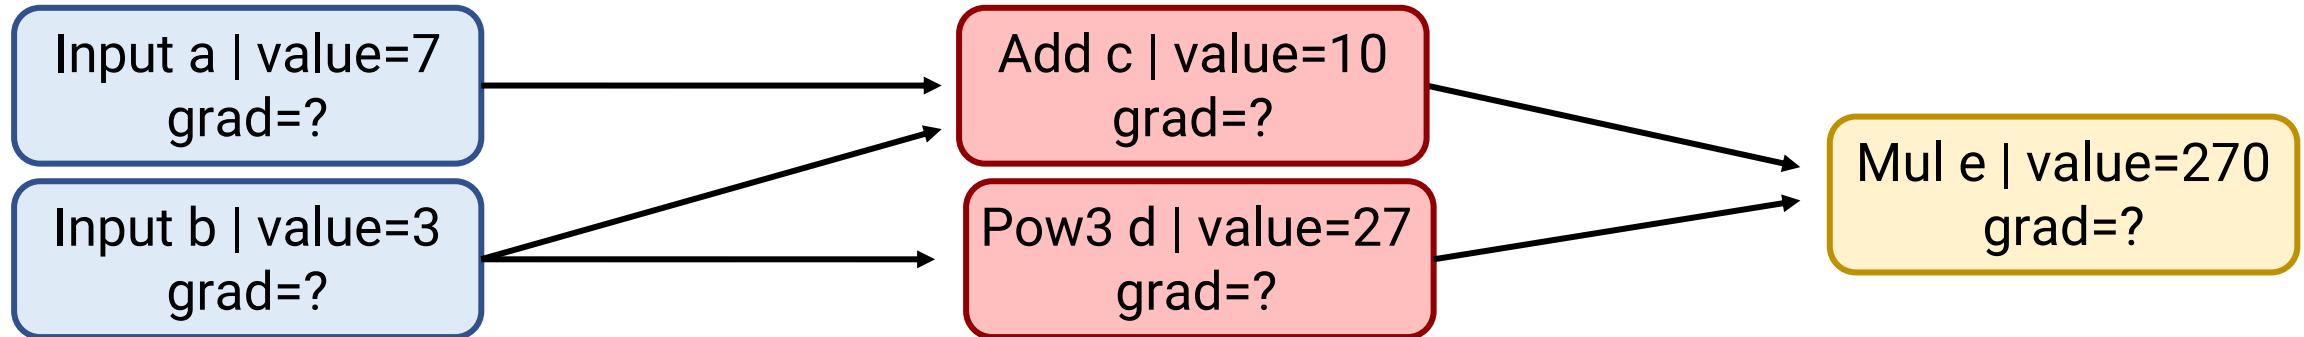

# Today's Plan

---

- The computation graph
- Backpropagation on trees
- Backpropagation on DAGs

# DAG Computation Graphs

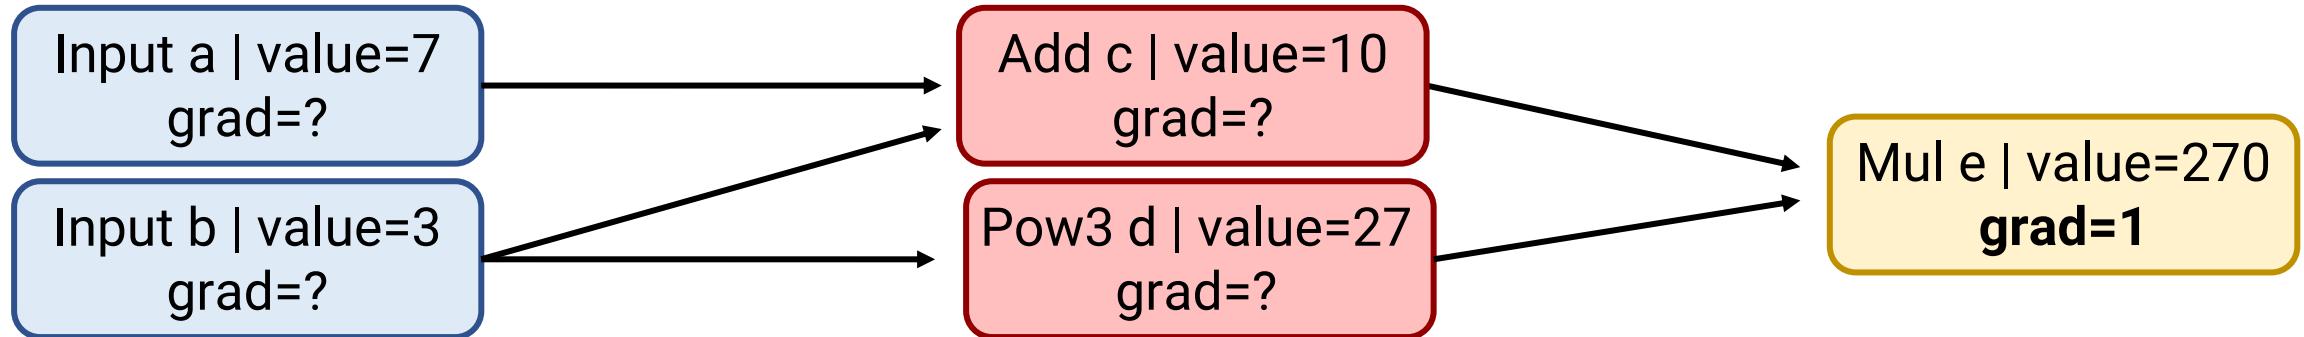

---

New function:  $(a + b) * b^3$  where  $a=7, b=3$

- This is no longer a tree!
- Still a directed acyclic graph
- Let's see why our previous algorithm fails

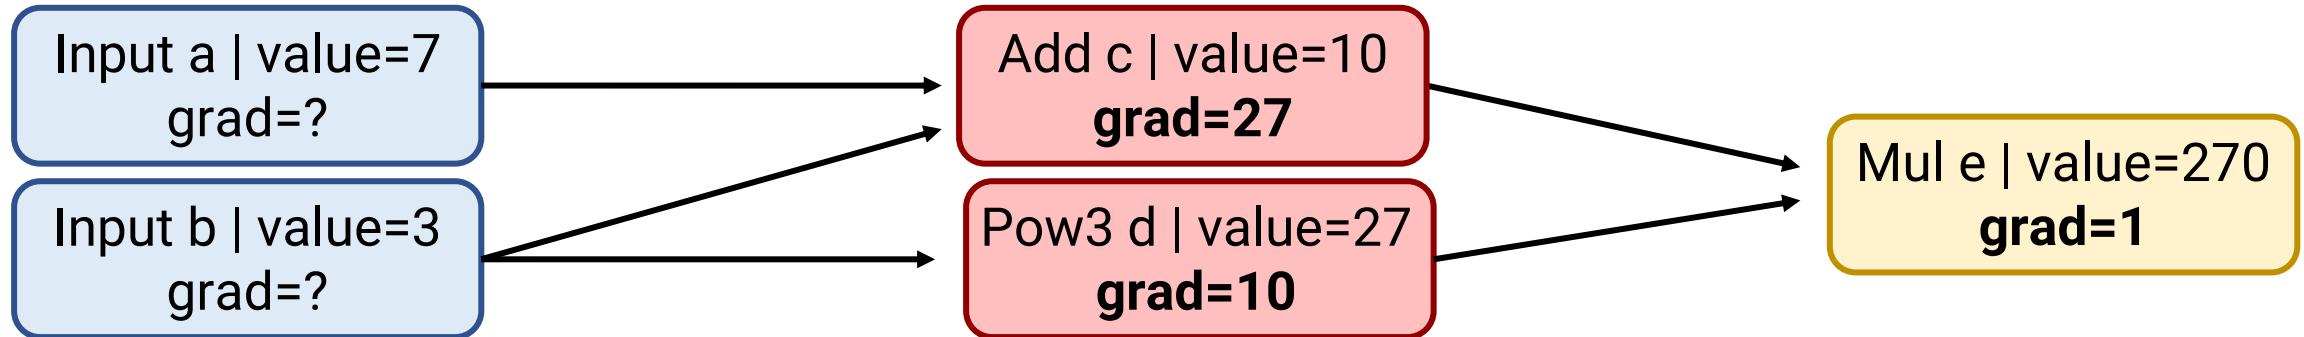

# DAG Computation Graphs

New function:  $(a + b) * b^3$  where  $a=7, b=3$

- Goal: Compute gradient  $[\partial e / \partial a, \partial e / \partial b]$
- Step 1: Base case:  $\partial e / \partial e = 1$

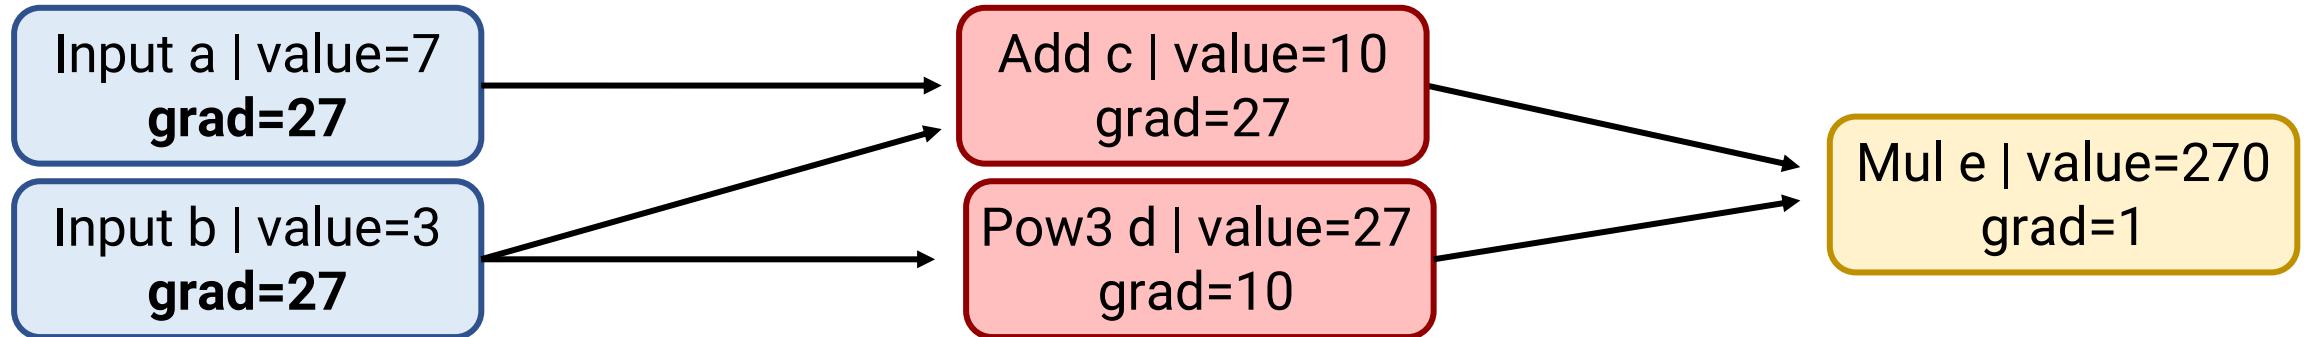

# DAG Computation Graphs

New function:  $(a + b) * b^3$  where  $a=7, b=3$

- Goal: Compute gradient  $[\partial f / \partial a, \partial f / \partial b]$
- Step 2: Distribute **Mul** (node e) gradient to children

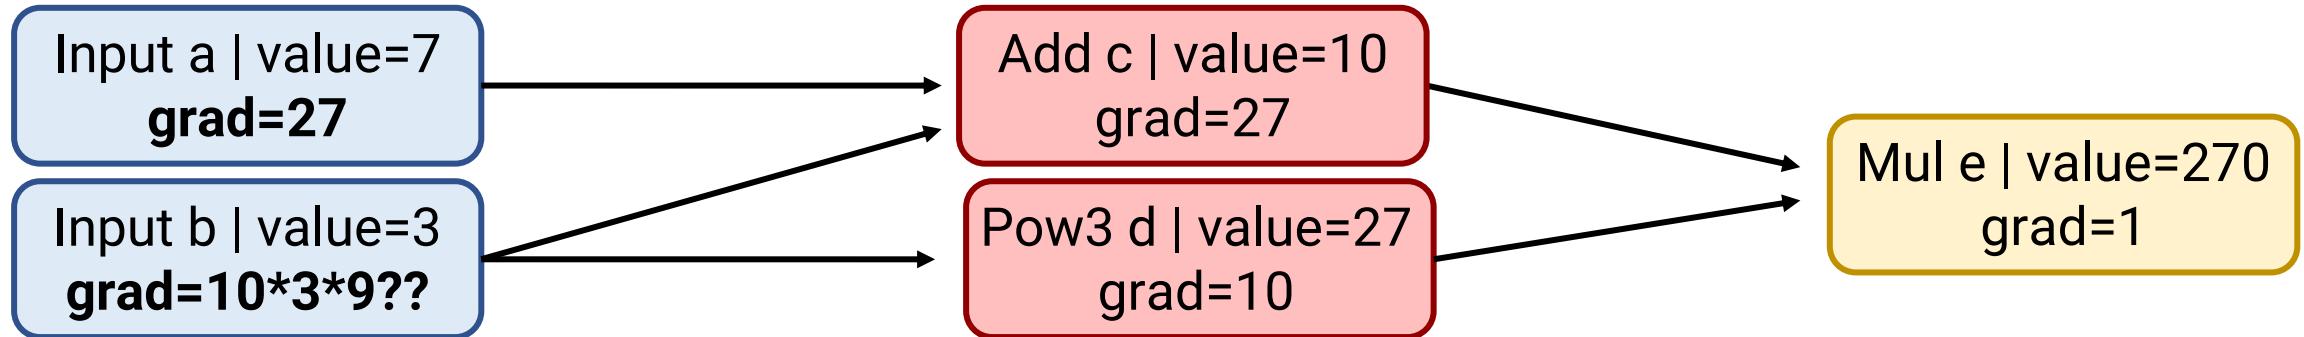

# DAG Computation Graphs

New function:  $(a + b) * b^3$  where  $a=7, b=3$

- Goal: Compute gradient  $[\partial e / \partial a, \partial e / \partial b]$
- Step 3: Distribute **Add** (node c) gradient to children

# DAG Computation Graphs

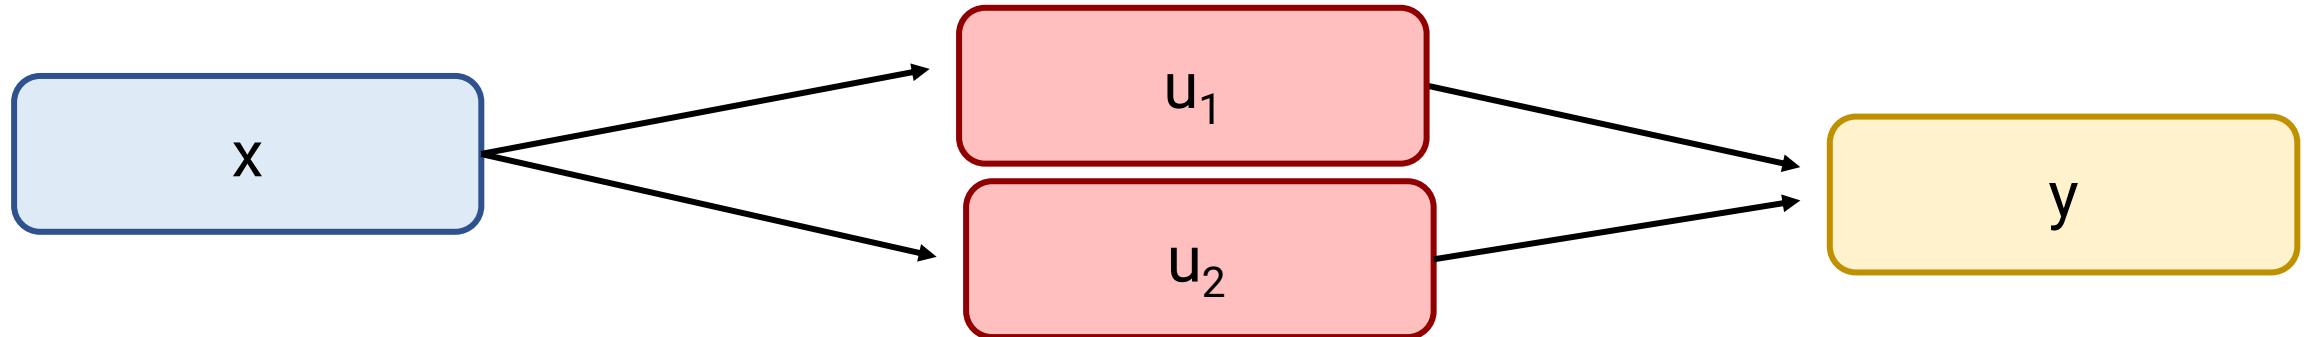

New function:  $(a + b) * b^3$  where  $a=7, b=3$

- Goal: Compute gradient  $[\partial e / \partial a, \partial e / \partial b]$
- Step 4: Distribute **Pow3** (node d) gradient to child
  - By Chain Rule: Child gets **parent's gradient**  $* p * \text{child}^{p-1}$
- Problem: We have overwritten the gradient from b to Add (node c)!

# Multivariate chain rule

---

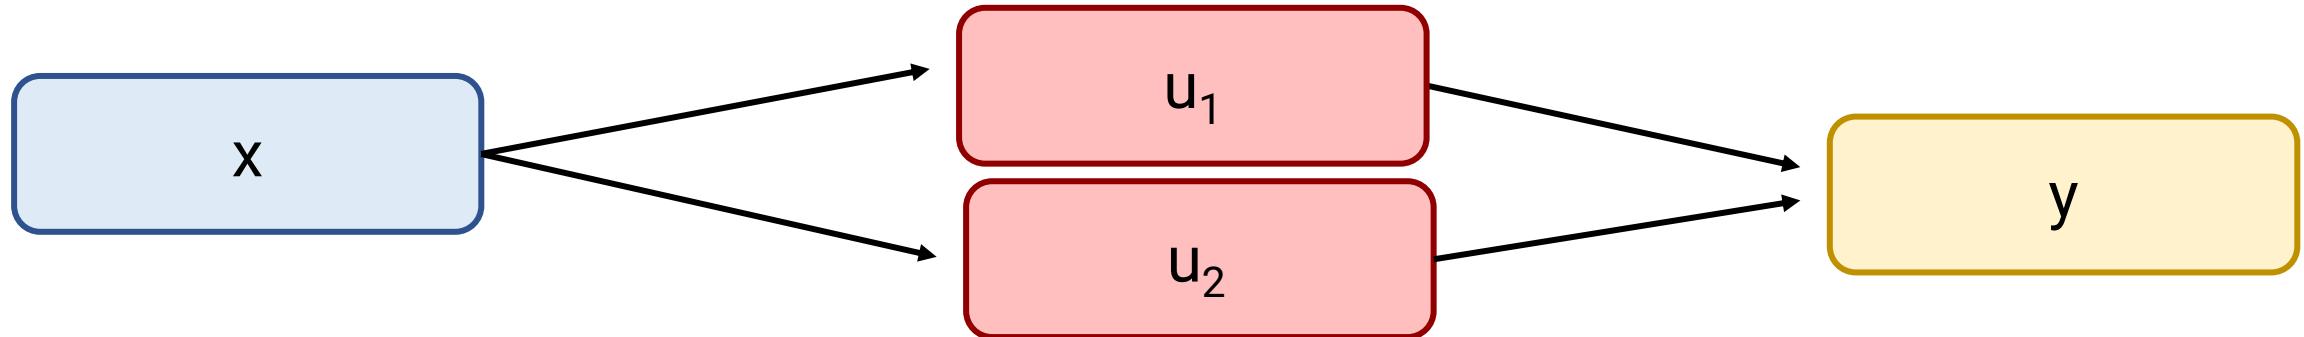

- Minimal example
  - $u_1$  and  $u_2$  depend on variable  $x$  (i.e.,  $x$  has two parents)
  - $y$  depends on both  $u_1$  and  $u_2$
- By Multivariate Chain Rule:  $\partial y / \partial x = \frac{\partial y}{\partial u_1} * \frac{\partial u_1}{\partial x} + \frac{\partial y}{\partial u_2} * \frac{\partial u_2}{\partial x}$ 
  - Changing  $x$  by epsilon changes each parent a bit; Effects add for small epsilon
  - Generalization of multiplying derivatives is matrix multiplication of Jacobians

*Dot product of  
[ $\partial y / \partial u_1, \partial y / \partial u_2$ ] &  
[ $\partial u_1 / \partial x, \partial u_2 / \partial x$ ]*

# Multivariate chain rule

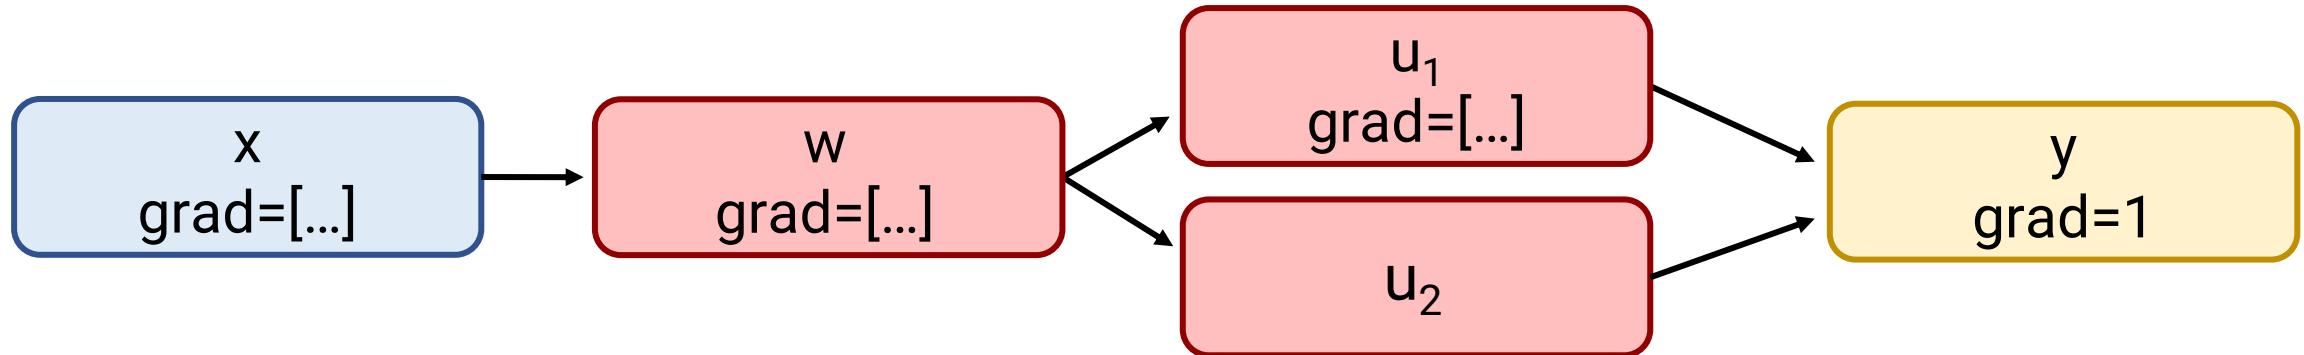

---

- Minimal example
  - $u_1$  and  $u_2$  depend on variable  $x$  (i.e.,  $x$  has two parents)
  - $y$  depends on both  $u_1$  and  $u_2$
- By Multivariate Chain Rule:  $\partial y / \partial x = \frac{\partial y}{\partial u_1} * \frac{\partial u_1}{\partial x} + \frac{\partial y}{\partial u_2} * \frac{\partial u_2}{\partial x}$
- `node.grad = sum over parents of parent.grad * ∂(parent)/∂(child)`
- At each parent node, run `child.grad += parent.grad * ∂(parent)/∂(child)`

# What order of traversal?

---

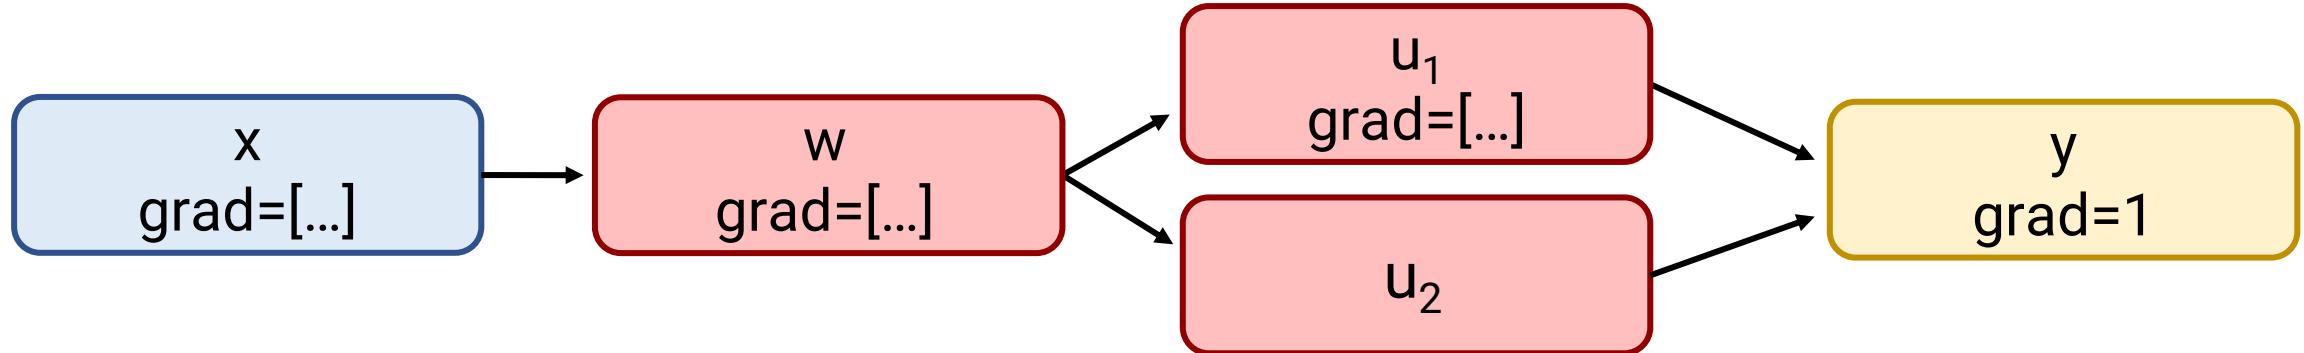

## Current code:

- `y.backward()`
  - `u1.backward()`
    - **w.backward()**
      - **x.backward()**
    - `u2.backward()`
      - **w.backward()**
        - **x.backward()**

- Going recursively double-counts
  - First call to `w.backward()` makes final `x.grad` too large
- Solution: **Topological sort the nodes**
  - Iterate in reverse order, starting from output
  - Ensures that we process each node after all of its parents

# What order of traversal?

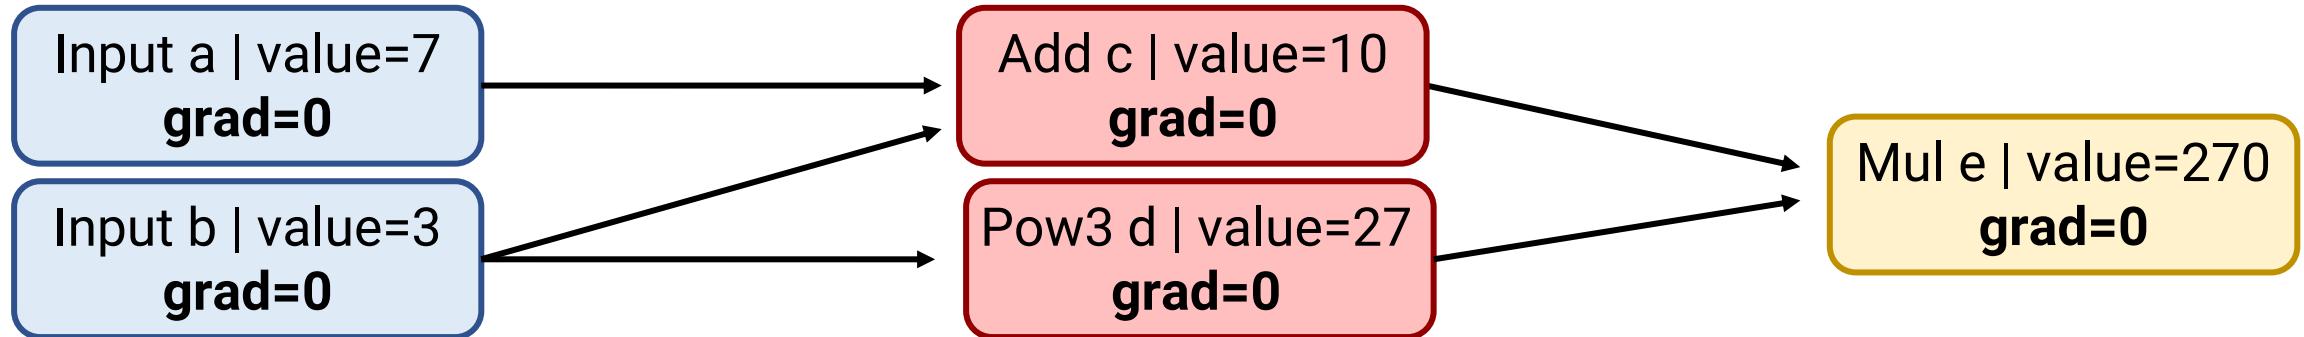

---

Better code:

- `topo_order = [x, w, u1, u2, y]`
- Iterate in reverse order:
  - `y.backward()`
  - `u2.backward()`
  - `u1.backward()`
  - `w.backward()`
  - `x.backward()`
- Going recursively double-counts
  - First call to `w.backward()` makes final `x.grad` too large
- Solution: **Topological sort the nodes**
  - Iterate in reverse order, starting from output
  - Ensures that we process each node after all of its parents

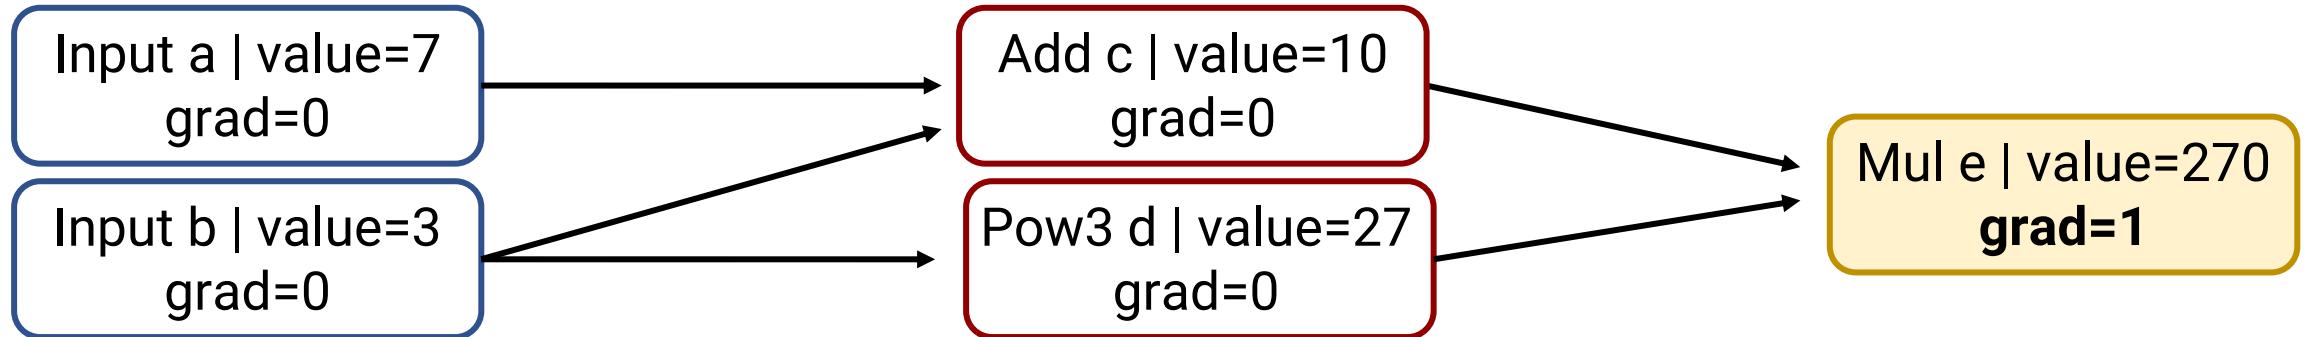

# Backpropagation on DAGs

New function:  $(a + b) * b^3$  where  $a=7, b=3$

- Goal: Compute gradient  $[\partial e / \partial a, \partial e / \partial b]$
- Topological sort: [a, b, c, d, e]
- Step 0: Initialize all gradients to 0

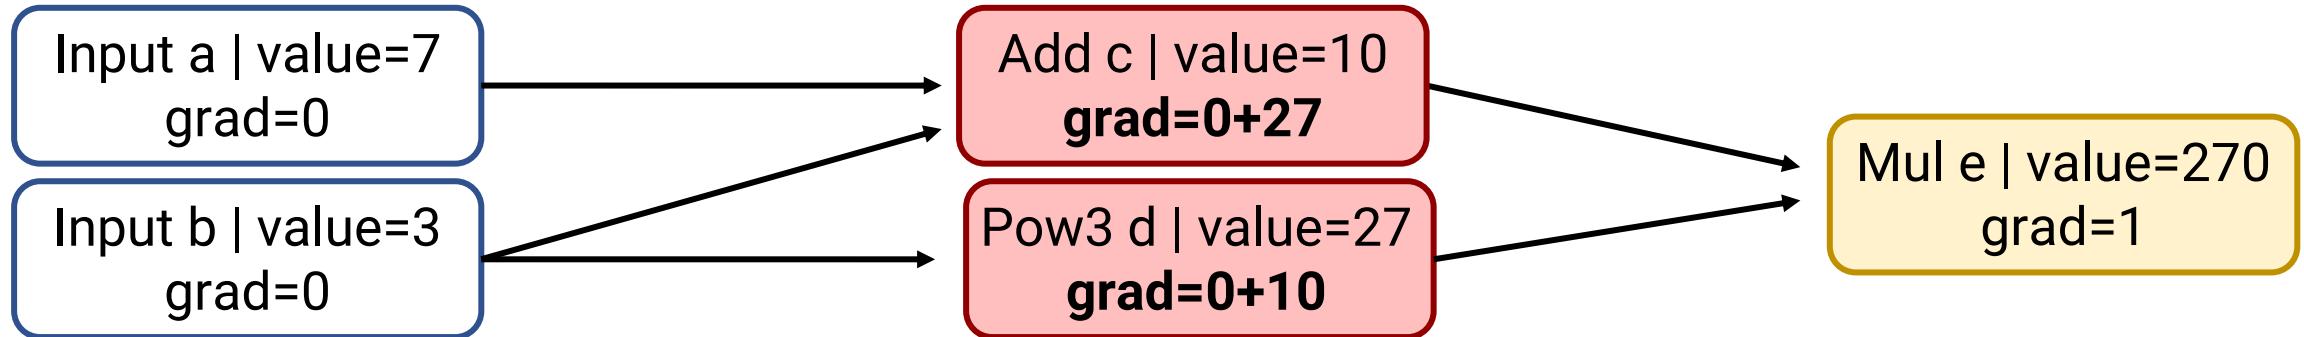

# Backpropagation on DAGs

New function:  $(a + b) * b^3$  where  $a=7, b=3$

- Goal: Compute gradient  $[\partial e / \partial a, \partial e / \partial b]$
- Topological sort: [a, b, c, d, e]
- Step 1: Base case:  $\partial e / \partial e = 1$

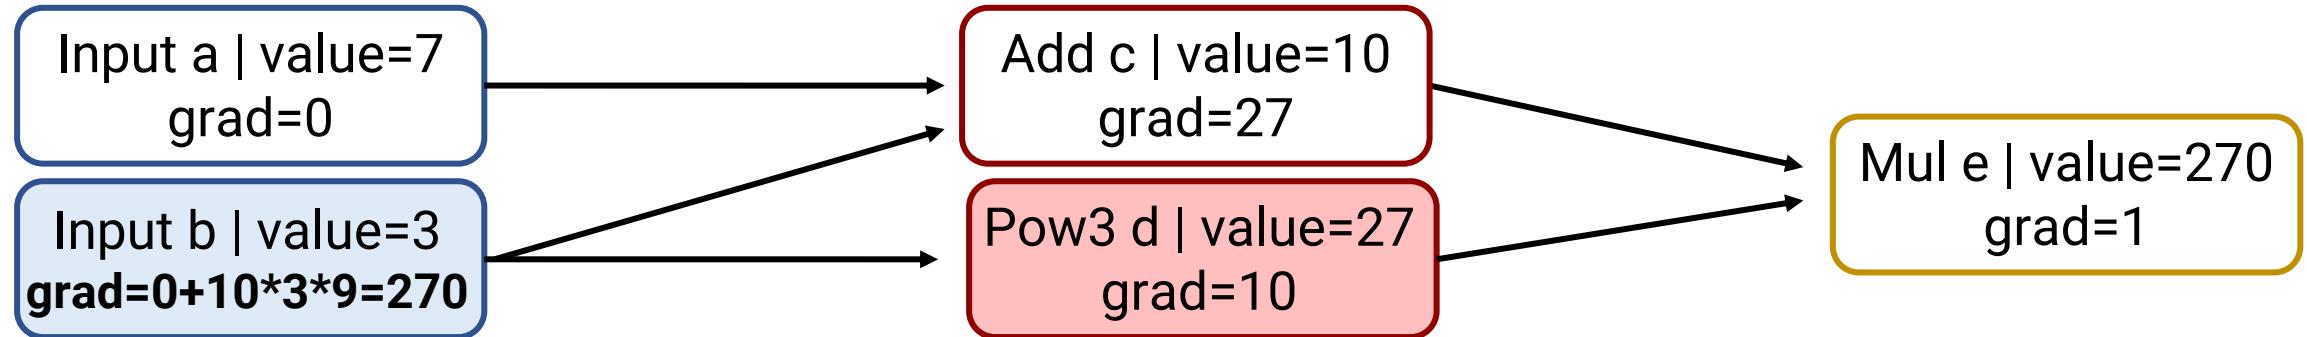

# Backpropagation on DAGs

New function:  $(a + b) * b^3$  where  $a=7, b=3$

- Goal: Compute gradient  $[\partial e / \partial a, \partial e / \partial b]$
- Topological sort, reversed: [e, d, c, b, a]
- Step 2: Propagate **Mul** node e to children

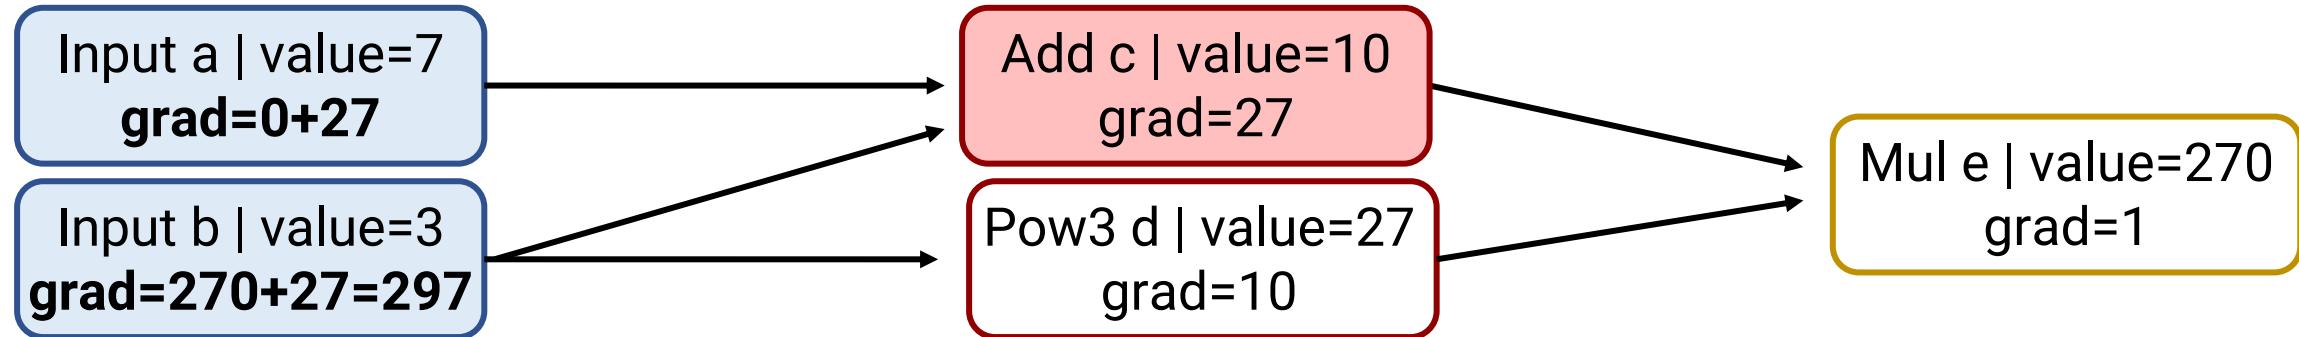

# Backpropagation on DAGs

New function:  $(a + b) * b^3$  where  $a=7, b=3$

- Goal: Compute gradient  $[\partial e / \partial a, \partial e / \partial b]$
- Topological sort, reversed: [e, d, c, b, a]
- Step 3: Propagate Pow3 node d to child

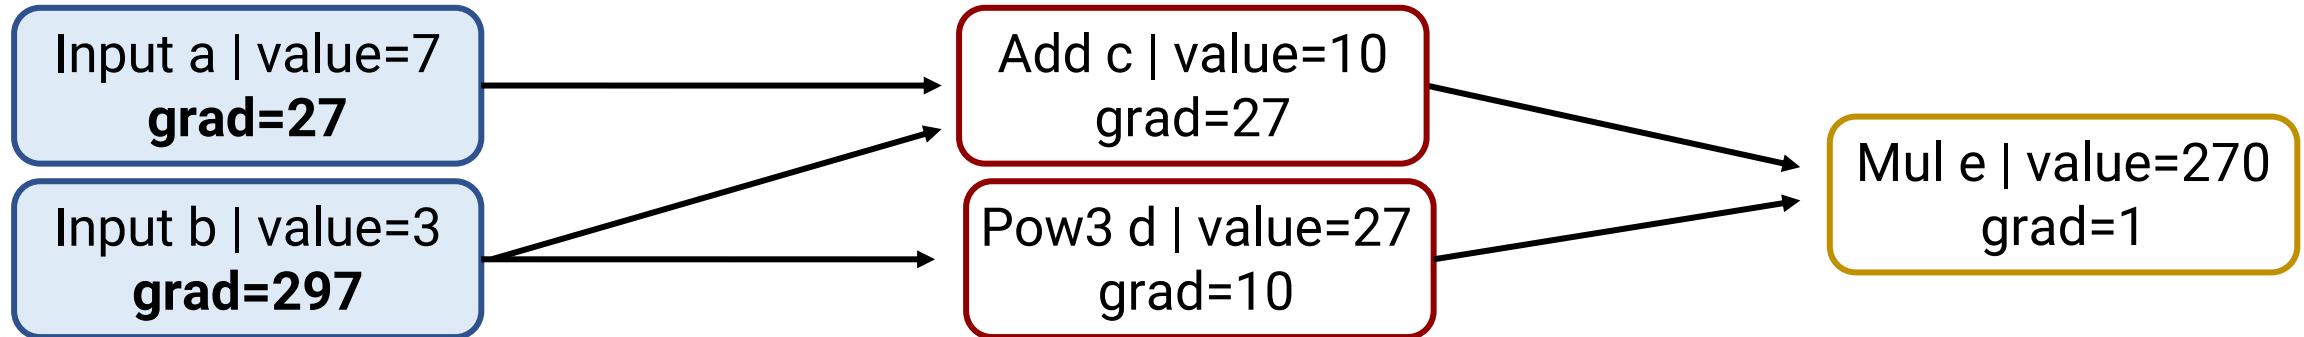

# Backpropagation on DAGs

New function:  $(a + b) * b^3$  where  $a=7, b=3$

- Goal: Compute gradient  $[\partial e / \partial a, \partial e / \partial b]$
- Topological sort, reversed: [e, d, c, b, a]
- Step 4: Propagate **Add** node c to children

# Backpropagation on DAGs

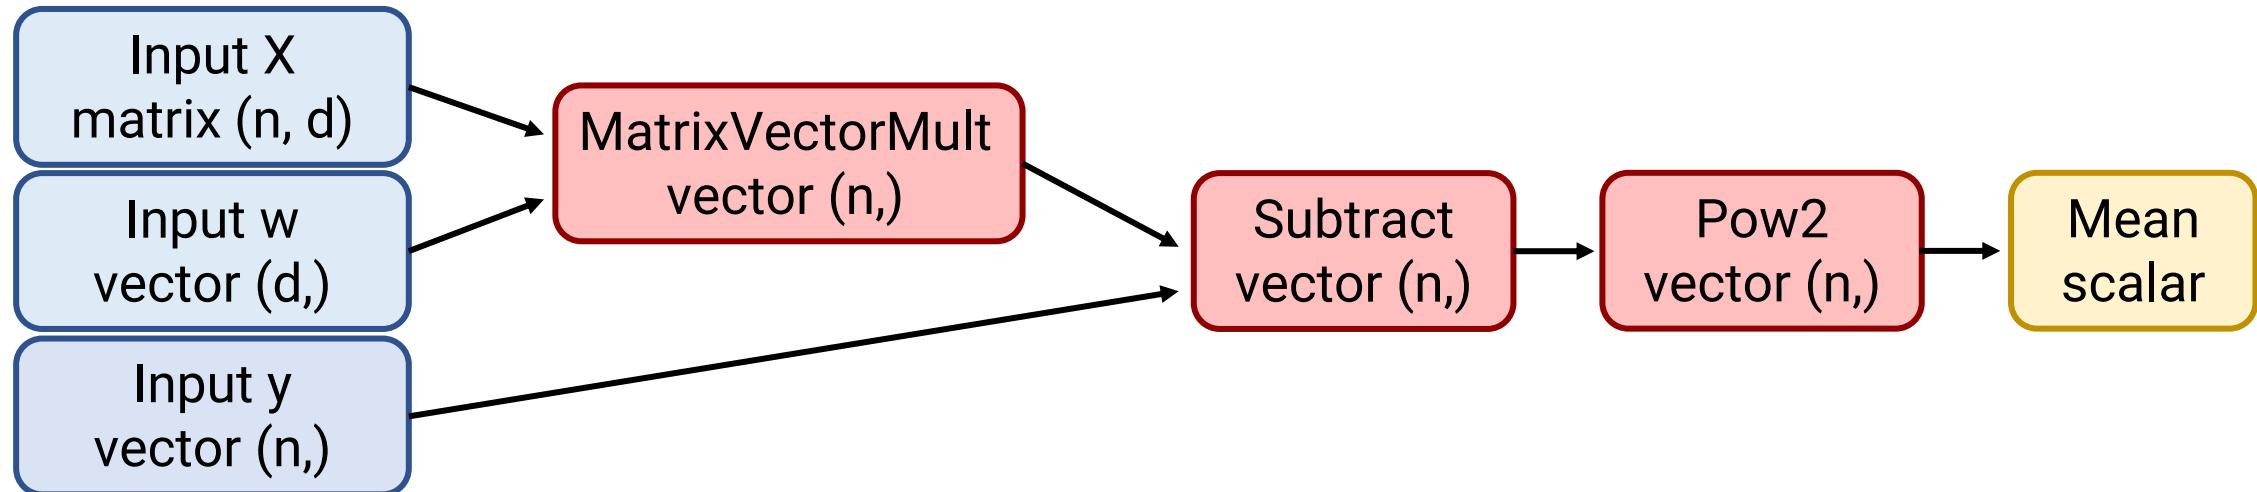

New function:  $(a + b) * b^3$  where  $a=7, b=3$

- Goal: Compute gradient  $[\partial e / \partial a, \partial e / \partial b]$
- Topological sort, reversed: [e, d, c, b, a]
- Step 5, 6: a.backward(), b.backward() do nothing

# Let's implement!

# Backpropagation for vectors and matrices

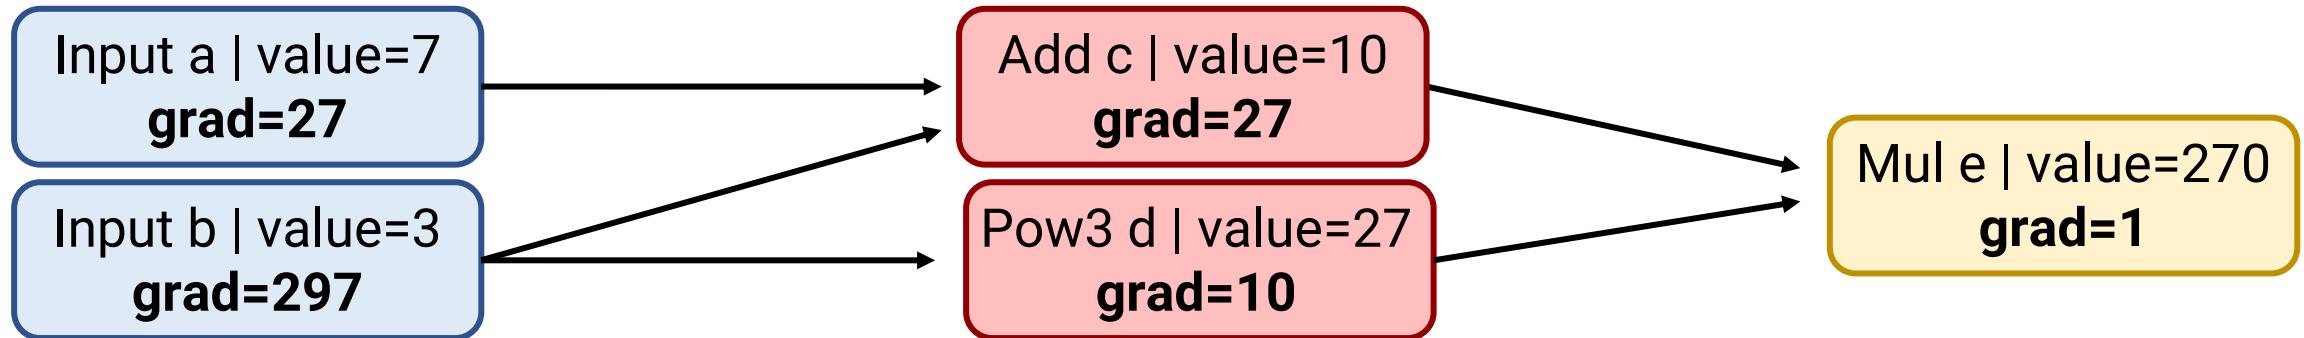

Computation graph for  $\text{mean}((Xw - y)^2)$ , i.e. Linear Regression

- Basically the same, but each node can be a vector or matrix!
  - Each node.grad stores  $\nabla_{\text{node}} \text{output}$
  - Parents know how to update  $\nabla_{\text{child}} \text{output}$  based on  $\nabla_{\text{parent}} \text{output}$

# Conclusion

---

- Backpropagation computes gradient of output with respect to all nodes in computation graph
  - Forward pass: Compute values of all nodes
  - Backward pass: Iterate through nodes in reverse order,  
At each parent node, run `child.grad += parent.grad *  $\partial(\text{parent})/\partial(\text{child})$`
- Big picture: Makes it easy to run gradient descent on arbitrary computation graphs
  - Easy to try new architectures for neural networks
